Package ‘foreach’

February 19, 2015

Type Package
Title Foreach looping construct for R
Version 1.4.2
Author Revolution Analytics, Steve Weston
Maintainer Revolution Analytics <packages@revolutionanalytics.com>
Description Support for the foreach looping construct. Foreach is an idiom that allows for iterating over elements in a collection, without the use of an explicit loop counter. This package in particular is intended to be used for its return value, rather than for its side effects. In that sense, it is similar to the standard lapply function, but doesn't require the evaluation of a function. Using foreach without side effects also facilitates executing the loop in parallel.
Depends R (>= 2.5.0)

The Foreach Package

Description
The foreach package provides a new looping construct for executing R code repeatedly. The main reason for using the foreach package is that it supports parallel execution. The foreach package can be used with a variety of different parallel computing systems, including NetWorkSpaces and snow. In addition, foreach can be used with iterators, which allows the data to be specified in a very flexible way.

Details
Further information is available in the following help topics:

- `foreach` Specify the variables to iterate over
- `%do%` Execute the R expression sequentially
- `%dopar%` Execute the R expression using the currently registered backend

To see a tutorial introduction to the foreach package, use `vignette("foreach")`. To see a demo of foreach computing the sinc function, use `demo(sincSEQ)`. Some examples (in addition to those in the help pages) are included in the "examples" directory of the foreach package. To list the files in the examples directory, use `list.files(system.file("examples", package="foreach"))`. To run the bootstrap example, use `source(system.file("examples", "bootseq.R", package="foreach"))`. For a complete list of functions with individual help pages, use `library(help="foreach")`.

Description
%do% and %dopar% are binary operators that operate on a foreach object and an R expression. The expression, `ex`, is evaluated multiple times in an environment that is created by the foreach object, and that environment is modified for each evaluation as specified by the foreach object. %do% evaluates the expression sequentially, while %dopar% evaluates it in parallel. The results of evaluating `ex` are returned as a list by default, but this can be modified by means of the `.combine` argument.
Usage

```r
globus foreach(...) .combine, .init, .final=FALSE, .inorder=FALSE,
    .multicombine=FALSE,
    .maxcombine=if (.multicombine) 100 else 2,
    .errorhandling=c('stop', 'remove', 'pass'),
    .packages=NULL, .export=NULL, .noexport=NULL,
    .verbose=TRUE)
```

when(cond)
```
e1 %:% e2
obj %do% ex
obj %dopar% ex
times(n)
```

Arguments

... one or more arguments that control how `ex` is evaluated. Named arguments specify the name and values of variables to be defined in the evaluation environment. An unnamed argument can be used to specify the number of times that `ex` should be evaluated. At least one argument must be specified in order to define the number of times `ex` should be executed.

`.combine` function that is used to process the tasks results as they generated. This can be specified as either a function or a non-empty character string naming the function. Specifying 'c' is useful for concatenating the results into a vector, for example. The values 'cbind' and 'rbind' can combine vectors into a matrix. The values '+' and '*' can be used to process numeric data. By default, the results are returned in a list.

`.init` initial value to pass as the first argument of the `.combine` function. This should not be specified unless `.combine` is also specified.

`.final` function of one argument that is called to return final result.

`.inorder` logical flag indicating whether the `.combine` function requires the task results to be combined in the same order that they were submitted. If the order is not important, then it setting `.inorder` to `FALSE` can give improved performance. The default value is `TRUE`.

`.multicombine` logical flag indicating whether the `.combine` function can accept more than two arguments. If an arbitrary `.combine` function is specified, by default, that function will always be called with two arguments. If it can take more than two arguments, then setting `.multicombine` to `TRUE` could improve the performance. The default value is `FALSE` unless the `.combine` function is `cbind`, `rbind`, or `c`, which are known to take more than two arguments.

`.maxcombine` maximum number of arguments to pass to the `.combine` function. This is only relevant if `.multicombine` is `TRUE`.

`.errorhandling` specifies how a task evaluation error should be handled. If the value is "stop", then execution will be stopped via the `stop` function if an error occurs. If the value is "remove", the result for that task will not be returned, or passed to the `.combine` function. If it is "pass", then the error object generated by task evaluation will be included with the rest of the results. It is assumed that the combine function (if specified) will be able to deal with the error object. The default value is "stop".
foreach

.packages character vector of packages that the tasks depend on. If `ex` requires an R package to be loaded, this option can be used to load that package on each of the workers. Ignored when used with `%do%`.

.export character vector of variables to export. This can be useful when accessing a variable that isn’t defined in the current environment. The default value is `NULL`.

.noexport character vector of variables to exclude from exporting. This can be useful to prevent variables from being exported that aren’t actually needed, perhaps because the symbol is used in a model formula. The default value is `NULL`.

.verbose logical flag enabling verbose messages. This can be very useful for troubleshooting.

.obj foreach object used to control the evaluation of `ex`.

.e1 foreach object to merge.

.e2 foreach object to merge.

.ex the R expression to evaluate.

.cond condition to evaluate.

.n number of times to evaluate the R expression.

Details

The `foreach` and `%do%%dopar%` operators provide a looping construct that can be viewed as a hybrid of the standard `for` loop and `lapply` function. It looks similar to the `for` loop, and it evaluates an expression, rather than a function (as in `lapply`), but it’s purpose is to return a value (a list, by default), rather than to cause side-effects. This facilitates parallelization, but looks more natural to people that prefer `for` loops to `lapply`.

The `%:%` operator is the nesting operator, used for creating nested foreach loops. Type `vignette("nested")` at the R prompt for more details.

Parallel computation depends upon a parallel backend that must be registered before performing the computation. The parallel backends available will be system-specific, but include `doParallel`, which uses R’s built-in `parallel` package, `doMC`, which uses the `multicore` package, and `doSNOW`. Each parallel backend has a specific registration function, such as `registerDoParallel` or `registerDoSNOW`.

The `times` function is a simple convenience function that calls `foreach`. It is useful for evaluating an R expression multiple times when there are no varying arguments. This can be convenient for resampling, for example.

See Also

`iter`

Examples

```r
# equivalent to rnorm(3)
times(3) %do% rnorm(1)

# equivalent to lapply(1:3, sqrt)
foreach(i=1:3) %do%
```
foreach-ext

Description

These functions are used to write parallel backends for the `foreach` package. They should not be used from normal scripts or packages that use the `foreach` package.
Usage

makeAccum(it)
accumulate(obj, result, tag, ...)
getexports(ex, e, env, good=character(0), bad=character(0))
ggetResult(obj, ...)
getErrorValue(obj, ...)
getErrorIndex(obj, ...)

Arguments

it          foreach iterator.
ex          call object to analyze.
e           local environment of the call object.
eenv        exported environment in which call object will be evaluated.
good       names of symbols that are being exported.
bad        names of symbols that are not being exported.
obj         foreach iterator object.
result      task result to accumulate.
tag         tag of task result to accumulate.
...          unused.

Note

These functions are likely to change in future versions of the foreach package. When they become more stable, they will be documented.

getDoParWorkers  Functions Providing Information on the doPar Backend

Description

The getDoParWorkers function returns the number of execution workers there are in the currently registered doPar backend. It can be useful when determining how to split up the work to be executed in parallel. A 1 is returned by default.

The getDoParRegistered function returns TRUE if a doPar backend has been registered, otherwise FALSE.

The getDoParName function returns the name of the currently registered doPar backend. A NULL is returned if no backend is registered.

The getDoParVersion function returns the version of the currently registered doPar backend. A NULL is returned if no backend is registered.
getDoSeqWorkers

Usage

getDoParWorkers()
getDoParRegistered()
getDoParName()
getDoParVersion()

Examples

cat(sprintf("%s backend is registered\n", 
    if(getDoParRegistered()) 'A' else 'No'))
cat(sprintf('Running with %d worker(s)\n', getDoParWorkers()))
(name <- getDoParName())
(ver <- getDoParVersion())
if (getDoParRegistered())
    cat(sprintf('Currently using %s [\%s]\n', name, ver))

getDoSeqWorkers

Functions Providing Information on the doSeq Backend

Description

The getDoSeqWorkers function returns the number of execution workers there are in the currently registered doSeq backend. A 1 is returned by default.

The getDoSeqRegistered function returns TRUE if a doSeq backend has been registered, otherwise FALSE.

The getDoSeqName function returns the name of the currently registered doSeq backend. A NULL is returned if no backend is registered.

The getDoSeqVersion function returns the version of the currently registered doSeq backend. A NULL is returned if no backend is registered.

Usage

getDoSeqWorkers()
getDoSeqRegistered()
getDoSeqName()
getDoSeqVersion()

Examples

cat(sprintf('%s backend is registered\n', 
    if(getDoSeqRegistered()) 'A' else 'No'))
cat(sprintf('Running with %d worker(s)\n', getDoSeqWorkers()))
(name <- getDoSeqName())
(ver <- getDoSeqVersion())
if (getDoSeqRegistered())
    cat(sprintf('Currently using %s [\%s]\n', name, ver))
registerDoSEQ

Description

The registerDoSEQ function is used to explicitly register a sequential parallel backend with the foreach package. This will prevent a warning message from being issued if the %dopar% function is called and no parallel backend has been registered.

Usage

registerDoSEQ()

See Also

registerDoSNOW

Examples

# specify that %dopar% should run sequentially
registerDoSEQ()

setDoPar

Description

The setDoPar function is used to register a parallel backend with the foreach package. This isn’t normally executed by the user. Instead, packages that provide a parallel backend provide a function named registerDoPar that calls setDoPar using the appropriate arguments.

Usage

setDoPar(fun, data=NULL, info=function(data, item) NULL)

Arguments

fun A function that implements the functionality of %dopar%.
data Data to passed to the registered function.
info Function that retrieves information about the backend.

See Also

%dopar%
The `setDoSeq` function is used to register a sequential backend with the `foreach` package. This isn’t normally executed by the user. Instead, packages that provide a sequential backend provide a function named `registerDoSeq` that calls `setDoSeq` using the appropriate arguments.

### Usage

```r
setDoSeq(fun, data=NULL, info=function(data, item) NULL)
```

### Arguments

- **fun**: A function that implements the functionality of `%dopar%`.
- **data**: Data to be passed to the registered function.
- **info**: Function that retrieves information about the backend.
