Package 'parameters'

May 14, 2024

Type Package

Title Processing of Model Parameters

Version 0.21.7

Maintainer Daniel Lüdecke <d.luedecke@uke.de>

Description Utilities for processing the parameters of various statistical models. Beyond computing p values, CIs, and other indices for a wide variety of models (see list of supported models using the function 'insight::supported_models()'), this package implements features like bootstrapping or simulating of parameters and models, feature reduction (feature extraction and variable selection) as well as functions to describe data and variable characteristics (e.g. skewness, kurtosis, smoothness or distribution).

bootstrap_model *Model bootstrapping*

Description

Bootstrap a statistical model n times to return a data frame of estimates.

Usage

```
bootstrap_model(model, iterations = 1000, ...)
## Default S3 method:
bootstrap_model(
 model,
 iterations = 1000,
  type = "ordinary",
 parallel = c("no", "multicore", "snow"),
 n_{cpus} = 1,
 verbose = FALSE,
  . . .
)
## S3 method for class 'merMod'
bootstrap_model(
 model,
  iterations = 1000,
  type = "parametric",
  parallel = c("no", "multicore", "snow"),
  n_{cpus} = 1,
  cluster = NULL,
```

```
verbose = FALSE,
...
```

Arguments

model	Statistical model.
iterations	The number of draws to simulate/bootstrap.
	Arguments passed to or from other methods.
type	Character string specifying the type of bootstrap. For mixed models of class merMod or glmmTMB, may be "parametric" (default) or "semiparametric" (see ?lme4::bootMer for details). For all other models, see argument sim in ?boot::boot (defaults to "ordinary").
parallel	The type of parallel operation to be used (if any).
n_cpus	Number of processes to be used in parallel operation.
verbose	Toggle warnings and messages.
cluster	Optional cluster when parallel = "snow". See ?lme4::bootMer for details.

Details

By default, boot::boot() is used to generate bootstraps from the model data, which are then used to update() the model, i.e. refit the model with the bootstrapped samples. For merMod objects (**lme4**) or models from **glmmTMB**, the lme4::bootMer() function is used to obtain bootstrapped samples. bootstrap_parameters() summarizes the bootstrapped model estimates.

Value

A data frame of bootstrapped estimates.

Using with emmeans

The output can be passed directly to the various functions from the **emmeans** package, to obtain bootstrapped estimates, contrasts, simple slopes, etc. and their confidence intervals. These can then be passed to model_parameter() to obtain standard errors, p-values, etc. (see example).

Note that that p-values returned here are estimated under the assumption of *translation equivariance*: that shape of the sampling distribution is unaffected by the null being true or not. If this assumption does not hold, p-values can be biased, and it is suggested to use proper permutation tests to obtain non-parametric p-values.

See Also

```
bootstrap_parameters(), simulate_model(), simulate_parameters()
```

Examples

```
model <- lm(mpg ~ wt + factor(cyl), data = mtcars)
b <- bootstrap_model(model)
print(head(b))
est <- emmeans::emmeans(b, consec ~ cyl)
print(model_parameters(est))
```

bootstrap_parameters Parameters bootstrapping

Description

Compute bootstrapped parameters and their related indices such as Confidence Intervals (CI) and p-values.

Usage

```
bootstrap_parameters(model, ...)
## Default S3 method:
bootstrap_parameters(
  model,
  iterations = 1000,
  centrality = "median",
  ci = 0.95,
  ci_method = "quantile",
  test = "p-value",
  ...
)
```

Arguments

model	Statistical model.
	Arguments passed to or from other methods.
iterations	The number of draws to simulate/bootstrap.
centrality	The point-estimates (centrality indices) to compute. Character (vector) or list with one or more of these options: "median", "mean", "MAP" (see map_estimate()), "trimmed" (which is just mean(x, trim = threshold)), "mode" or "all".
ci	Value or vector of probability of the CI (between 0 and 1) to be estimated. Default to 0.95 (95%).

ci_method	The type of index used for Credible Interval. Can be "ETI" (default, see eti()), "HDI" (see hdi()), "BCI" (see bci()), "SPI" (see spi()), or "SI" (see si()).
test	The indices to compute. Character (vector) with one or more of these options: "p-value" (or "p"), "p_direction" (or "pd"), "rope", "p_map", "equivalence_test" (or "equitest"), "bayesfactor" (or "bf") or "all" to compute all tests. For each "test", the corresponding bayestestR function is called (e.g. bayestestR::rope() or bayestestR::p_direction()) and its results included in the summary out- put.

Details

This function first calls bootstrap_model() to generate bootstrapped coefficients. The resulting replicated for each coefficient are treated as "distribution", and is passed to bayestestR::describe_posterior() to calculate the related indices defined in the "test" argument.

Note that that p-values returned here are estimated under the assumption of *translation equivariance*: that shape of the sampling distribution is unaffected by the null being true or not. If this assumption does not hold, p-values can be biased, and it is suggested to use proper permutation tests to obtain non-parametric p-values.

Value

A data frame summarizing the bootstrapped parameters.

Using with emmeans

The output can be passed directly to the various functions from the **emmeans** package, to obtain bootstrapped estimates, contrasts, simple slopes, etc. and their confidence intervals. These can then be passed to model_parameter() to obtain standard errors, p-values, etc. (see example).

Note that that p-values returned here are estimated under the assumption of *translation equivariance*: that shape of the sampling distribution is unaffected by the null being true or not. If this assumption does not hold, p-values can be biased, and it is suggested to use proper permutation tests to obtain non-parametric p-values.

```
set.seed(2)
model <- lm(Sepal.Length ~ Species * Petal.Width, data = iris)
b <- bootstrap_parameters(model)</pre>
```

```
print(b)
est <- emmeans::emmeans(b, trt.vs.ctrl ~ Species)
print(model_parameters(est))</pre>
```

```
ci.default
```

```
Confidence Intervals (CI)
```

Description

ci() attempts to return confidence intervals of model parameters.

Usage

```
## Default S3 method:
ci(x, ci = 0.95, dof = NULL, method = NULL, ...)
## S3 method for class 'glmmTMB'
ci(
    x,
    ci = 0.95,
    dof = NULL,
    method = "wald",
    component = "all",
    verbose = TRUE,
    ...
)
## S3 method for class 'merMod'
ci(x, ci = 0.95, dof = NULL, method = "wald", iterations = 500, ...)
```

Arguments

х	A statistical model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
dof	Number of degrees of freedom to be used when calculating confidence intervals. If NULL (default), the degrees of freedom are retrieved by calling degrees_of_freedom() with approximation method defined in method. If not NULL, use this argument to override the default degrees of freedom used to compute confidence intervals.
method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi- dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details.

ci.default

•••	Additional arguments
component	Model component for which parameters should be shown. See the documenta- tion for your object's class in model_parameters() or p_value() for further details.
verbose	Toggle warnings and messages.
iterations	The number of bootstrap replicates. Only applies to models of class merMod when method=boot.

Value

A data frame containing the CI bounds.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

• Applies to *non-Bayesian models*. For *linear models*, CIs computed using the Wald method (SE and a *t-distribution with residual df*); p-values computed using the Wald method with a *t-distribution with residual df*. For other models, CIs computed using the Wald method (SE and a *normal distribution*); p-values computed using the Wald method with a *normal distribution*.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

"ml1"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with m-l-1 approximated df*); p-values computed using the Wald method with a *t-distribution with m-l-1 approximated df*. See ci_ml1().

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

"uniroot"

 Applies to non-Bayesian models of class glmmTMB. CIs computed by profiling the likelihood curve for a parameter, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a normal-distribution (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

ci.default

• Applies to *all models* (*including Bayesian models*). For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

"hdi"

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

• Applies to *Bayesian models* with proper priors. CIs computed as *support intervals* comparing the posterior samples against the prior samples; p-values are based on the *probability of direction*. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

```
library(parameters)
data(Salamanders, package = "glmmTMB")
model <- glmmTMB::glmmTMB(
    count ~ spp + mined + (1 | site),
    ziformula = ~mined,
    family = poisson(),
    data = Salamanders
)
ci(model)
ci(model, component = "zi")</pre>
```

ci_betwithin

Description

Approximation of degrees of freedom based on a "between-within" heuristic.

Usage

```
ci_betwithin(model, ci = 0.95, ...)
```

dof_betwithin(model)

p_value_betwithin(model, dof = NULL, ...)

Arguments

model	A mixed model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
	Additional arguments
dof	Degrees of Freedom.

Details

Small Sample Cluster corrected Degrees of Freedom:

Inferential statistics (like p-values, confidence intervals and standard errors) may be biased in mixed models when the number of clusters is small (even if the sample size of level-1 units is high). In such cases it is recommended to approximate a more accurate number of degrees of freedom for such inferential statistics (see *Li and Redden 2015*). The *Between-within* denominator degrees of freedom approximation is recommended in particular for (generalized) linear mixed models with repeated measurements (longitudinal design). dof_betwithin() implements a heuristic based on the between-within approach. **Note** that this implementation does not return exactly the same results as shown in *Li and Redden 2015*, but similar.

Degrees of Freedom for Longitudinal Designs (Repeated Measures):

In particular for repeated measure designs (longitudinal data analysis), the *between-within* heuristic is likely to be more accurate than simply using the residual or infinite degrees of freedom, because dof_betwithin() returns different degrees of freedom for within-cluster and betweencluster effects.

Value

A data frame.

ci_kenward

See Also

dof_betwithin() is a small helper-function to calculate approximated degrees of freedom of model parameters, based on the "between-within" heuristic.

Examples

```
if (require("lme4")) {
   data(sleepstudy)
   model <- lmer(Reaction ~ Days + (1 + Days | Subject), data = sleepstudy)
   dof_betwithin(model)
   p_value_betwithin(model)
}</pre>
```

ci_kenward Kenward-Roger approximation for SEs, CIs and p-values

Description

An approximate F-test based on the Kenward-Roger (1997) approach.

Usage

```
ci_kenward(model, ci = 0.95)
```

dof_kenward(model)

p_value_kenward(model, dof = NULL)

se_kenward(model)

Arguments

model	A statistical model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
dof	Degrees of Freedom.

Details

Inferential statistics (like p-values, confidence intervals and standard errors) may be biased in mixed models when the number of clusters is small (even if the sample size of level-1 units is high). In such cases it is recommended to approximate a more accurate number of degrees of freedom for such inferential statistics. Unlike simpler approximation heuristics like the "m-l-1" rule (dof_ml1), the Kenward-Roger approximation is also applicable in more complex multilevel designs, e.g. with cross-classified clusters. However, the "m-l-1" heuristic also applies to generalized mixed models, while approaches like Kenward-Roger or Satterthwaite are limited to linear mixed models only.

Value

A data frame.

References

Kenward, M. G., & Roger, J. H. (1997). Small sample inference for fixed effects from restricted maximum likelihood. Biometrics, 983-997.

See Also

dof_kenward() and se_kenward() are small helper-functions to calculate approximated degrees of freedom and standard errors for model parameters, based on the Kenward-Roger (1997) approach.

dof_satterthwaite() and dof_ml1() approximate degrees of freedom based on Satterthwaite's method or the "m-l-1" rule.

Examples

```
if (require("lme4", quietly = TRUE)) {
  model <- lmer(Petal.Length ~ Sepal.Length + (1 | Species), data = iris)
  p_value_kenward(model)
}</pre>
```

ci_ml1

"m-l-1" approximation for SEs, CIs and p-values

Description

Approximation of degrees of freedom based on a "m-l-1" heuristic as suggested by Elff et al. (2019).

Usage

```
ci_ml1(model, ci = 0.95, ...)
dof_ml1(model)
p_value_ml1(model, dof = NULL, ...)
```

ci_ml1

Arguments

model	A mixed model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
	Additional arguments
dof	Degrees of Freedom.

Details

Small Sample Cluster corrected Degrees of Freedom:

Inferential statistics (like p-values, confidence intervals and standard errors) may be biased in mixed models when the number of clusters is small (even if the sample size of level-1 units is high). In such cases it is recommended to approximate a more accurate number of degrees of freedom for such inferential statistics (see *Li and Redden 2015*). The *m-l-1* heuristic is such an approach that uses a t-distribution with fewer degrees of freedom (dof_ml1()) to calculate p-value_ml1()) and confidence intervals (ci(method = "ml1")).

Degrees of Freedom for Longitudinal Designs (Repeated Measures):

In particular for repeated measure designs (longitudinal data analysis), the *m*-*l*-1 heuristic is likely to be more accurate than simply using the residual or infinite degrees of freedom, because $dof_ml1()$ returns different degrees of freedom for within-cluster and between-cluster effects.

Limitations of the "m-l-1" Heuristic:

Note that the "m-l-1" heuristic is not applicable (or at least less accurate) for complex multilevel designs, e.g. with cross-classified clusters. In such cases, more accurate approaches like the Kenward-Roger approximation (dof_kenward()) is recommended. However, the "m-l-1" heuristic also applies to generalized mixed models, while approaches like Kenward-Roger or Satterthwaite are limited to linear mixed models only.

Value

A data frame.

```

ci_satterthwaite Satterthwaite approximation for SEs, CIs and p-values

Description

An approximate F-test based on the Satterthwaite (1946) approach.

Usage

```
ci_satterthwaite(model, ci = 0.95, ...)
```

```
dof_satterthwaite(model)
```

```
p_value_satterthwaite(model, dof = NULL, ...)
```

se_satterthwaite(model)

Arguments

model	A statistical model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
	Additional arguments
dof	Degrees of Freedom.

Details

Inferential statistics (like p-values, confidence intervals and standard errors) may be biased in mixed models when the number of clusters is small (even if the sample size of level-1 units is high). In such cases it is recommended to approximate a more accurate number of degrees of freedom for such inferential statistics. Unlike simpler approximation heuristics like the "m-l-1" rule (dof_ml1), the Satterthwaite approximation is also applicable in more complex multilevel designs. However, the "m-l-1" heuristic also applies to generalized mixed models, while approaches like Kenward-Roger or Satterthwaite are limited to linear mixed models only.

Value

A data frame.

```
if (require("lme4", quietly = TRUE)) {
  model <- lmer(Petal.Length ~ Sepal.Length + (1 | Species), data = iris)
  p_value_satterthwaite(model)
}</pre>
```

cluster_analysis Cluster Analysis

Description

Compute hierarchical or kmeans cluster analysis and return the group assignment for each observation as vector.

Usage

```
cluster_analysis(
    x,
    n = NULL,
    method = "kmeans",
    include_factors = FALSE,
    standardize = TRUE,
    verbose = TRUE,
    distance_method = "euclidean",
    hclust_method = "complete",
    kmeans_method = "Hartigan-Wong",
    dbscan_eps = 15,
    iterations = 100,
    ....
)
```

Arguments

x	A data frame (with at least two variables), or a matrix (with at least two columns).
n	Number of clusters used for supervised cluster methods. If NULL, the number of clusters to extract is determined by calling n_clusters(). Note that this argument does not apply for unsupervised clustering methods like dbscan, hdbscan, mixture, pvclust, or pamk.
method	Method for computing the cluster analysis. Can be "kmeans" (default; k-means using kmeans()), "hkmeans" (hierarchical k-means using factoextra::hkmeans()), pam (K-Medoids using cluster::pam()), pamk (K-Medoids that finds out the number of clusters), "hclust" (hierarchical clustering using hclust() or pvclust::pvclust()) dbscan (DBSCAN using dbscan::dbscan()), hdbscan (Hierarchical DBSCAN using dbscan::hdbscan()), or mixture (Mixture modeling using mclust::Mclust(), which requires the user to run library(mclust) before).
include_factors	3
	Logical, if TRUE, factors are converted to numerical values in order to be in- cluded in the data for determining the number of clusters. By default, factors are removed, because most methods that determine the number of clusters need numeric input only.
standardize	Standardize the dataframe before clustering (default).
verbose	Toggle warnings and messages.
distance_method	1
	<pre>Distance measure to be used for methods based on distances (e.g., when method = "hclust" for hierarchical clustering. For other methods, such as "kmeans", this argument will be ignored). Must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". See dist() and pvclust::pvclust() for more information.</pre>
hclust_method	Agglomeration method to be used when method = "hclust" or method = "hkmeans" (for hierarchical clustering). This should be one of "ward", "ward.D2", "single", "complete", "average", "mcquitty", "median" or "centroid". Default is "complete" (see hclust()).
kmeans_method	Algorithm used for calculating kmeans cluster. Only applies, if method = "kmeans". May be one of "Hartigan-Wong" (default), "Lloyd" (used by SPSS), or "MacQueen". See kmeans() for details on this argument.
dbscan_eps	The eps argument for DBSCAN method. See n_clusters_dbscan().
iterations	The number of replications.
	Arguments passed to or from other methods.

Details

The print() and plot() methods show the (standardized) mean value for each variable within each cluster. Thus, a higher absolute value indicates that a certain variable characteristic is more pronounced within that specific cluster (as compared to other cluster groups with lower absolute mean values).

Clusters classification can be obtained via print(x, newdata = NULL, ...).

cluster_analysis

Value

The group classification for each observation as vector. The returned vector includes missing values, so it has the same length as nrow(x).

Note

There is also a plot()-method implemented in the see-package.

cluster_centers Find the cluster centers in your data

Description

For each cluster, computes the mean (or other indices) of the variables. Can be used to retrieve the centers of clusters. Also returns the within Sum of Squares.

Usage

```
cluster_centers(data, clusters, fun = mean, ...)
```

Arguments

data	A data.frame.
clusters	A vector with clusters assignments (must be same length as rows in data).
fun	What function to use, mean by default.
	Other arguments to be passed to or from other functions.

Value

A dataframe containing the cluster centers. Attributes include performance statistics and distance between each observation and its respective cluster centre.

cluster_discrimination

Examples

```
k <- kmeans(iris[1:4], 3)
cluster_centers(iris[1:4], clusters = k$cluster)
cluster_centers(iris[1:4], clusters = k$cluster, fun = median)</pre>
```

cluster_discrimination

Compute a linear discriminant analysis on classified cluster groups

Description

Computes linear discriminant analysis (LDA) on classified cluster groups, and determines the goodness of classification for each cluster group. See MASS::lda() for details.

Usage

```
cluster_discrimination(x, cluster_groups = NULL, ...)
```

Arguments

х	A data frame
cluster_groups	Group classification of the cluster analysis, which can be retrieved from the cluster_analysis() function.
	Other arguments to be passed to or from.

See Also

n_clusters() to determine the number of clusters to extract, cluster_analysis() to compute a cluster analysis and performance::check_clusterstructure() to check suitability of data for clustering.

```
# Retrieve group classification from hierarchical cluster analysis
clustering <- cluster_analysis(iris[, 1:4], n = 3)
# Goodness of group classification</pre>
```

```
cluster_discrimination(clustering)
```

cluster_meta

Description

One of the core "issue" of statistical clustering is that, in many cases, different methods will give different results. The **metaclustering** approach proposed by *easystats* (that finds echoes in *consensus clustering*; see Monti et al., 2003) consists of treating the unique clustering solutions as a ensemble, from which we can derive a probability matrix. This matrix contains, for each pair of observations, the probability of being in the same cluster. For instance, if the 6th and the 9th row of a dataframe has been assigned to a similar cluster by 5 our of 10 clustering methods, then its probability of being grouped together is 0.5.

Usage

```
cluster_meta(list_of_clusters, rownames = NULL, ...)
```

Arguments

list_of_clusters

	A list of vectors with the clustering assignments from various methods.
rownames	An optional vector of row.names for the matrix.
	Currently not used.

Details

Metaclustering is based on the hypothesis that, as each clustering algorithm embodies a different prism by which it sees the data, running an infinite amount of algorithms would result in the emergence of the "true" clusters. As the number of algorithms and parameters is finite, the probabilistic perspective is a useful proxy. This method is interesting where there is no obvious reasons to prefer one over another clustering method, as well as to investigate how robust some clusters are under different algorithms.

This metaclustering probability matrix can be transformed into a dissimilarity matrix (such as the one produced by dist()) and submitted for instance to hierarchical clustering (hclust()). See the example below.

Value

A matrix containing all the pairwise (between each observation) probabilities of being clustered together by the methods.

```
data <- iris[1:4]
rez1 <- cluster_analysis(data, n = 2, method = "kmeans")</pre>
```

cluster_performance

```
rez2 <- cluster_analysis(data, n = 3, method = "kmeans")
rez3 <- cluster_analysis(data, n = 6, method = "kmeans")
list_of_clusters <- list(rez1, rez2, rez3)
m <- cluster_meta(list_of_clusters)
# Visualize matrix without reordering
heatmap(m, Rowv = NA, Colv = NA, scale = "none") # Without reordering
# Reordered heatmap
heatmap(m, scale = "none")
# Extract 3 clusters
predict(m, n = 3)
# Convert to dissimilarity
d <- as.dist(abs(m - 1))
model <- hclust(d)
plot(model, hang = -1)</pre>
```

cluster_performance Performance of clustering models

Description

Compute performance indices for clustering solutions.

Usage

```
cluster_performance(model, ...)
## S3 method for class 'kmeans'
cluster_performance(model, ...)
## S3 method for class 'hclust'
cluster_performance(model, data, clusters, ...)
## S3 method for class 'dbscan'
cluster_performance(model, data, ...)
```

```
## S3 method for class 'parameters_clusters'
cluster_performance(model, ...)
```

Arguments

model	Cluster model.
	Arguments passed to or from other methods.
data	A data.frame.
clusters	A vector with clusters assignments (must be same length as rows in data).

Examples

```
# kmeans
model <- kmeans(iris[1:4], 3)</pre>
cluster_performance(model)
# hclust
data <- iris[1:4]</pre>
model <- hclust(dist(data))</pre>
clusters <- cutree(model, 3)</pre>
rez <- cluster_performance(model, data, clusters)</pre>
rez
# DBSCAN
model <- dbscan::dbscan(iris[1:4], eps = 1.45, minPts = 10)</pre>
rez <- cluster_performance(model, iris[1:4])</pre>
rez
# Retrieve performance from parameters
params <- model_parameters(kmeans(iris[1:4], 3))</pre>
cluster_performance(params)
```

compare_parameters Compare model parameters of multiple models

Description

Compute and extract model parameters of multiple regression models. See model_parameters() for further details.

Usage

```
compare_parameters(
  ...,
  ci = 0.95,
 effects = "fixed",
  component = "conditional",
  standardize = NULL,
  exponentiate = FALSE,
  ci_method = "wald",
  p_adjust = NULL,
  select = NULL,
  column_names = NULL,
  pretty_names = TRUE,
  coefficient_names = NULL,
  keep = NULL,
  drop = NULL,
  include_reference = FALSE,
```

```
groups = NULL,
 verbose = TRUE
)
compare_models(
  . . . ,
 ci = 0.95,
 effects = "fixed",
  component = "conditional",
  standardize = NULL,
 exponentiate = FALSE,
  ci_method = "wald",
  p_adjust = NULL,
  select = NULL,
  column_names = NULL,
  pretty_names = TRUE,
  coefficient_names = NULL,
  keep = NULL,
  drop = NULL,
  include_reference = FALSE,
 groups = NULL,
 verbose = TRUE
)
```

Arguments

	One or more regression model objects, or objects returned by model_parameters(). Regression models may be of different model types. Model objects may be passed comma separated, or as a list. If model objects are passed with names or the list has named elements, these names will be used as column names.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
effects	Should parameters for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. If the calculation of random effects parameters takes too long, you may use effects = "fixed".
component	Model component for which parameters should be shown. See documentation for related model class in model_parameters().
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly :
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized.

	 Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
ci_method	Method for computing degrees of freedom for p-values and confidence intervals (CI). See documentation for related model class in model_parameters().
p_adjust	Character vector, if not NULL, indicates the method to adjust p-values. See <pre>stats::p.adjust()</pre> for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).
select	Determines which columns and and which layout columns are printed. There are three options for this argument:
	 Selecting columns by name or index select can be a character vector (or numeric index) of column names that should be printed. There are two pre-defined options for selecting columns: select = "minimal" prints coefficients, confidence intervals and p-values, while select = "short" prints coefficients, standard errors and p-values.
	2. A string expression with layout pattern select is a string with "tokens" enclosed in braces. These tokens will be replaced by their associated columns, where the selected columns will be collapsed into one column. However, it is possible to create multiple columns as well. Following tokens are replaced by the related coefficients or statistics: {estimate}, {se}, {ci} (or {ci_low} and {ci_high}), {p} and {stars}. The token {ci} will be replaced by {ci_low}, {ci_high}. Furthermore, a separates values into new cells/columns. If format = "html", a br> inserts a line break inside a cell. See 'Examples'.
	 A string indicating a pre-defined layout select can be one of the following string values, to create one of the fol- lowing pre-defined column layouts:
	 "ci": Estimates and confidence intervals, no asterisks for p-values. This is equivalent to select = "{estimate} ({ci})".
	 "se": Estimates and standard errors, no asterisks for p-values. This is equivalent to select = "{estimate} ({se})".
	 "ci_p": Estimates, confidence intervals and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({ci})".
	 "se_p": Estimates, standard errors and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({se})"

- "ci_p2": Estimates, confidence intervals and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({ci})|{p}".
- "se_p2": Estimate, standard errors and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({se})|{p}".

For model_parameters(), glue-like syntax is still experimental in the case of more complex models (like mixed models) and may not return expected results.

- column_names Character vector with strings that should be used as column headers. Must be of same length as number of models in
- pretty_names Can be TRUE, which will return "pretty" (i.e. more human readable) parameter names. Or "labels", in which case value and variable labels will be used as parameters names. The latter only works for "labelled" data, i.e. if the data used to fit the model had "label" and "labels" attributes. See also section *Global Options to Customize Messages when Printing*.

coefficient_names

Character vector with strings that should be used as column headers for the coefficient column. Must be of same length as number of models in ..., or length 1. If length 1, this name will be used for all coefficient columns. If NULL, the name for the coefficient column will detected automatically (as in model_parameters()).

keep Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the "Parameter" column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.

drop See keep.

include_reference

Logical, if TRUE, the reference level of factors will be added to the parameters table. This is only relevant for models with categorical predictors. The coefficient for the reference level is always 0 (except when exponentiate = TRUE, then the coefficient will be 1), so this is just for completeness.

groups Named list, can be used to group parameters in the printed output. List elements may either be character vectors that match the name of those parameters that belong to one group, or list elements can be row numbers of those parameter rows that should belong to one group. The names of the list elements will be used as group names, which will be inserted as "header row". A possible use case

	might be to emphasize focal predictors and control variables, see 'Examples'.
	non-matching parameters will be added to the end.
verbose	Toggle warnings and messages.

Details

This function is in an early stage and does not yet cope with more complex models, and probably does not yet properly render all model components. It should also be noted that when including models with interaction terms, not only do the values of the parameters change, but so does their meaning (from main effects, to simple slopes), thereby making such comparisons hard. Therefore, you should not use this function to compare models with interaction terms with models without interaction terms.

Value

A data frame of indices related to the model's parameters.

```
data(iris)
lm1 <- lm(Sepal.Length ~ Species, data = iris)</pre>
lm2 <- lm(Sepal.Length ~ Species + Petal.Length, data = iris)</pre>
compare_parameters(lm1, lm2)
# custom style
compare_parameters(lm1, lm2, select = "{estimate}{stars} ({se})")
# custom style, in HTML
result <- compare_parameters(lm1, lm2, select = "{estimate}<br>({se})|{p}")
print_html(result)
data(mtcars)
m1 <- lm(mpg ~ wt, data = mtcars)</pre>
m2 <- glm(vs ~ wt + cyl, data = mtcars, family = "binomial")</pre>
compare_parameters(m1, m2)
# exponentiate coefficients, but not for lm
compare_parameters(m1, m2, exponentiate = "nongaussian")
# change column names
compare_parameters("linear model" = m1, "logistic reg." = m2)
compare_parameters(m1, m2, column_names = c("linear model", "logistic reg."))
# or as list
compare_parameters(list(m1, m2))
compare_parameters(list("linear model" = m1, "logistic reg." = m2))
```

convert_efa_to_cfa Conversion between EFA results and CFA structure

Description

Enables a conversion between Exploratory Factor Analysis (EFA) and Confirmatory Factor Analysis (CFA) lavaan-ready structure.

Usage

```
convert_efa_to_cfa(model, ...)
## S3 method for class 'fa'
convert_efa_to_cfa(
   model,
   threshold = "max",
   names = NULL,
   max_per_dimension = NULL,
   ...
)
```

efa_to_cfa(model, ...)

Arguments

model	An EFA model (e.g., a psych::fa object).	
	Arguments passed to or from other methods.	
threshold	A value between 0 and 1 indicates which (absolute) values from the loadings should be removed. An integer higher than 1 indicates the n strongest loadings to retain. Can also be "max", in which case it will only display the maximum loading per variable (the most simple structure).	
names	Vector containing dimension names.	
max_per_dimension		
	Maximum number of variables to keep per dimension.	

Value

Converted index.

```
library(parameters)
data(attitude)
efa <- psych::fa(attitude, nfactors = 3)</pre>
```

```
model1 <- efa_to_cfa(efa)
model2 <- efa_to_cfa(efa, threshold = 0.3)
model3 <- efa_to_cfa(efa, max_per_dimension = 2)
suppressWarnings(anova(
    lavaan::cfa(model1, data = attitude),
    lavaan::cfa(model2, data = attitude),
    lavaan::cfa(model3, data = attitude)
))</pre>
```

degrees_of_freedom Degrees of Freedom (DoF)

Description

Estimate or extract degrees of freedom of models parameters.

Usage

```
degrees_of_freedom(model, ...)
```

```
## Default S3 method:
degrees_of_freedom(model, method = "analytical", ...)
```

dof(model, ...)

Arguments

model	A statistical model.
	Currently not used.
method	Can be "analytical" (default, DoFs are estimated based on the model type), "residual" in which case they are directly taken from the model if available
	(for Bayesian models, the goal (looking for help to make it happen) would be to refit the model as a frequentist one before extracting the DoFs), "ml1" (see
	<pre>dof_ml1()), "betwithin" (see dof_betwithin()), "satterthwaite" (see dof_satterthwaite()),</pre>
	of those methods, whichever succeeds. See 'Details'.

Details

Methods for calculating degrees of freedom:

 "analytical" for models of class lmerMod, Kenward-Roger approximated degrees of freedoms are calculated, for other models, n-k (number of observations minus number of parameters).

- "residual" tries to extract residual degrees of freedom, and returns Inf if residual degrees of freedom could not be extracted.
- "any" first tries to extract residual degrees of freedom, and if these are not available, extracts analytical degrees of freedom.
- "nokr" same as "analytical", but does not Kenward-Roger approximation for models of class lmerMod. Instead, always uses n-k to calculate df for any model.
- "normal" returns Inf.
- "wald" returns residual df for models with t-statistic, and Inf for all other models.
- "kenward" calls dof_kenward().
- "satterthwaite" calls dof_satterthwaite().
- "ml1" calls dof_ml1().
- "betwithin" calls dof_betwithin().

For models with z-statistic, the returned degrees of freedom for model parameters is Inf (unless method = "ml1" or method = "betwithin"), because there is only one distribution for the related test statistic.

Note

In many cases, degrees_of_freedom() returns the same as df.residuals(), or n-k (number of observations minus number of parameters). However, degrees_of_freedom() refers to the model's *parameters* degrees of freedom of the distribution for the related test statistic. Thus, for models with z-statistic, results from degrees_of_freedom() and df.residuals() differ. Furthermore, for other approximation methods like "kenward" or "satterthwaite", each model parameter can have a different degree of freedom.

```
model <- lm(Sepal.Length ~ Petal.Length * Species, data = iris)</pre>
dof(model)
model <- glm(vs ~ mpg * cyl, data = mtcars, family = "binomial")</pre>
dof(model)
if (require("lme4", quietly = TRUE)) {
 model <- lmer(Sepal.Length ~ Petal.Length + (1 | Species), data = iris)</pre>
 dof(model)
}
if (require("rstanarm", quietly = TRUE)) {
 model <- stan_glm(</pre>
    Sepal.Length ~ Petal.Length * Species,
    data = iris,
   chains = 2,
    refresh = 0
 )
 dof(model)
}
```

display.parameters_model

Print tables in different output formats

Description

Prints tables (i.e. data frame) in different output formats. print_md() is a alias for display(format = "markdown"), print_html() is a alias for display(format = "html"). print_table() is for specific use cases only, and currently only works for compare_parameters() objects.

Usage

```
## S3 method for class 'parameters_model'
display(
  object,
  format = "markdown",
  pretty_names = TRUE,
  split_components = TRUE,
  select = NULL,
  caption = NULL,
  subtitle = NULL,
  footer = NULL,
  align = NULL,
  digits = 2,
  ci_digits = digits,
  p_digits = 3,
  footer_digits = 3,
  ci_brackets = c("(", ")"),
  show_sigma = FALSE,
  show_formula = FALSE,
  zap_small = FALSE,
  font_size = "100%",
  line_padding = 4,
  column_labels = NULL,
  include_reference = FALSE,
  verbose = TRUE,
  . . .
)
## S3 method for class 'parameters_sem'
display(
  object,
  format = "markdown",
  digits = 2,
  ci_digits = digits,
  p_digits = 3,
  ci_brackets = c("(", ")"),
```

```
. . .
)
## S3 method for class 'parameters_efa_summary'
display(object, format = "markdown", digits = 3, ...)
## S3 method for class 'parameters_efa'
display(
  object,
  format = "markdown",
  digits = 2,
  sort = FALSE,
  threshold = NULL,
  labels = NULL,
  . . .
)
## S3 method for class 'equivalence_test_lm'
display(object, format = "markdown", digits = 2, ...)
## S3 method for class 'parameters_model'
format(
  х,
  pretty_names = TRUE,
  split_components = TRUE,
  select = NULL,
  digits = 2,
  ci_digits = digits,
  p_digits = 3,
  ci_width = NULL,
  ci_brackets = NULL,
  zap_small = FALSE,
  format = NULL,
  groups = NULL,
  include_reference = FALSE,
  . . .
)
## S3 method for class 'parameters_model'
print_html(
  х,
  pretty_names = TRUE,
  split_components = TRUE,
  select = NULL,
  caption = NULL,
  subtitle = NULL,
  footer = NULL,
  align = NULL,
```

```
digits = 2,
  ci_digits = digits,
  p_digits = 3,
  footer_digits = 3,
  ci_brackets = c("(", ")"),
  show_sigma = FALSE,
  show_formula = FALSE,
  zap_small = FALSE,
  groups = NULL,
  font_size = "100%",
  line_padding = 4,
  column_labels = NULL,
  include_reference = FALSE,
  verbose = TRUE,
  . . .
)
## S3 method for class 'parameters_model'
print_md(
  х,
  pretty_names = TRUE,
  split_components = TRUE,
  select = NULL,
  caption = NULL,
  subtitle = NULL,
  footer = NULL,
  align = NULL,
  digits = 2,
  ci_digits = digits,
  p_digits = 3,
  footer_digits = 3,
  ci_brackets = c("(", ")"),
  show_sigma = FALSE,
  show_formula = FALSE,
  zap_small = FALSE,
  groups = NULL,
  include_reference = FALSE,
  verbose = TRUE,
  . . .
)
print_table(x, digits = 2, p_digits = 3, theme = "default", ...)
```

Arguments

object	An object returned by model_parameters(), simulate_parameters(), equivalence_test()
	or principal_components().
format	String, indicating the output format. Can be "markdown" or "html".

pretty_names Can be TRUE, which will return "pretty" (i.e. more human readable) parameter names. Or "labels", in which case value and variable labels will be used as parameters names. The latter only works for "labelled" data, i.e. if the data used to fit the model had "label" and "labels" attributes. See also section *Global Options to Customize Messages when Printing*.

split_components

Logical, if TRUE (default), For models with multiple components (zero-inflation, smooth terms, ...), each component is printed in a separate table. If FALSE, model parameters are printed in a single table and a Component column is added to the output.

- select Determines which columns and and which layout columns are printed. There are three options for this argument:
 - 1. Selecting columns by name or index

select can be a character vector (or numeric index) of column names that should be printed. There are two pre-defined options for selecting columns: select = "minimal" prints coefficients, confidence intervals and p-values, while select = "short" prints coefficients, standard errors and p-values.

- 2. A string expression with layout pattern select is a string with "tokens" enclosed in braces. These tokens will be replaced by their associated columns, where the selected columns will be collapsed into one column. However, it is possible to create multiple columns as well. Following tokens are replaced by the related coefficients or statistics: {estimate}, {se}, {ci} (or {ci_low} and {ci_high}), {p} and {stars}. The token {ci} will be replaced by {ci_low}, {ci_high}. Furthermore, a | separates values into new cells/columns. If format = "html", a
 inserts a line break inside a cell. See 'Examples'.
- 3. A string indicating a pre-defined layout select can be one of the following string values, to create one of the following pre-defined column layouts:
 - "ci": Estimates and confidence intervals, no asterisks for p-values. This is equivalent to select = "{estimate} ({ci})".
 - "se": Estimates and standard errors, no asterisks for p-values. This is equivalent to select = "{estimate} ({se})".
 - "ci_p": Estimates, confidence intervals and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({ci})".
 - "se_p": Estimates, standard errors and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({se})"..
 - "ci_p2": Estimates, confidence intervals and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({ci})|{p}".
 - "se_p2": Estimate, standard errors and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({se})|{p}".

For model_parameters(), glue-like syntax is still experimental in the case of more complex models (like mixed models) and may not return expected results.

caption Table caption as string. If NULL, depending on the model, either a default caption or no table caption is printed. Use caption = "" to suppress the table caption.

subtitle	Table title (same as caption) and subtitle, as strings. If NULL, no title or subtitle is printed, unless it is stored as attributes (table_title, or its alias table_caption, and table_subtitle). If x is a list of data frames, caption may be a list of table captions, one for each table.
footer	Can either be FALSE or an empty string (i.e. "") to suppress the footer, NULL to print the default footer, or a string. The latter will combine the string value with the default footer.
align digits, ci_digi	Only applies to HTML tables. May be one of "left", "right" or "center". ts, p_digits
	Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).
footer_digits	Number of decimal places for values in the footer summary.
ci_brackets	Logical, if TRUE (default), CI-values are encompassed in square brackets (else in parentheses).
show_sigma	Logical, if TRUE, adds information about the residual standard deviation.
show_formula	Logical, if TRUE, adds the model formula to the output.
zap_small	Logical, if TRUE, small values are rounded after digits decimal places. If FALSE, values with more decimal places than digits are printed in scientific notation.
font_size	For HTML tables, the font size.
line_padding	For HTML tables, the distance (in pixel) between lines.
column_labels	Labels of columns for HTML tables. If NULL, automatic column names are generated. See 'Examples'.
include_referer	ice
	Logical, if TRUE, the reference level of factors will be added to the parameters table. This is only relevant for models with categorical predictors. The coefficient for the reference level is always \emptyset (except when exponentiate = TRUE, then the coefficient will be 1), so this is just for completeness.
verbose	Toggle messages and warnings.
	Arguments passed to or from other methods.
sort	Sort the loadings.
threshold	A value between 0 and 1 indicates which (absolute) values from the loadings should be removed. An integer higher than 1 indicates the n strongest loadings to retain. Can also be "max", in which case it will only display the maximum loading per variable (the most simple structure).
labels	A character vector containing labels to be added to the loadings data. Usually, the question related to the item.
x	An object returned by model_parameters().
ci_width	Minimum width of the returned string for confidence intervals. If not NULL and width is larger than the string's length, leading whitespaces are added to the string. If width="auto", width will be set to the length of the longest string.
groups	Named list, can be used to group parameters in the printed output. List elements
--------	--
	long to one group, or list elements can be row numbers of those parameters that be
	that should belong to one group. The names of the list elements will be used
	as group names, which will be inserted as "header row". A possible use case
	might be to emphasize focal predictors and control variables, see 'Examples'.
	Parameters will be re-ordered according to the order used in groups, while all
	non-matching parameters will be added to the end.
theme	String, indicating the table theme. Can be one of "default", "grid", "striped"
	"bootstrap" or "darklines".

Details

display() is useful when the table-output from functions, which is usually printed as formatted text-table to console, should be formatted for pretty table-rendering in markdown documents, or if knitted from rmarkdown to PDF or Word files. See vignette for examples.

print_table() is a special function for compare_parameters() objects, which prints the output as a formatted HTML table. It is still somewhat experimental, thus, only a fixed layout-style is available at the moment (columns for estimates, confidence intervals and p-values). However, it is possible to include other model components, like zero-inflation, or random effects in the table. See 'Examples'. An alternative is to set engine = "tt" in print_html() to use the *tinytable* package for creating HTML tables.

Value

If format = "markdown", the return value will be a character vector in markdown-table format. If format = "html", an object of class gt_tbl. For print_table(), an object of class tinytable is returned.

print_table(out)
```

dominance_analysis Dominance Analysis

Description

Computes Dominance Analysis Statistics and Designations

Usage

```
dominance_analysis(
  model,
  sets = NULL,
  all = NULL,
  conditional = TRUE,
  complete = TRUE,
  quote_args = NULL,
  contrasts = model$contrasts,
  ...
)
```

Arguments

model	A model object supported by performance::r2(). See 'Details'.
sets	A (named) list of formula objects with no left hand side/response. If the list has names, the name provided each element will be used as the label for the set. Unnamed list elements will be provided a set number name based on its position among the sets as entered.
	Predictors in each formula are bound together as a set in the dominance analysis and dominance statistics and designations are computed for the predictors to- gether. Predictors in sets must be present in the model submitted to the model argument and cannot be in the all argument.
all	A formula with no left hand side/response.
	Predictors in the formula are included in each subset in the dominance analy- sis and the R2 value associated with them is subtracted from the overall value. Predictors in all must be present in the model submitted to the model argument and cannot be in the sets argument.
conditional	Logical. If FALSE then conditional dominance matrix is not computed.
	If conditional dominance is not desired as an importance criterion, avoiding computing the conditional dominance matrix can save computation time.
complete	Logical. If FALSE then complete dominance matrix is not computed.
	If complete dominance is not desired as an importance criterion, avoiding com- puting complete dominance designations can save computation time.
quote_args	A character vector of arguments in the model submitted to model to quote() prior to submitting to the dominance analysis. This is necessary for data masked arguments (e.g., weights) to prevent them from being evaluated before being applied to the model and causing an error.
contrasts	A named list of contrasts used by the model object. This list is required in order for the correct mapping of parameters to predictors in the output when the model creates indicator codes for factor variables using insight::get_modelmatrix(). By default, the contrast element from the model object submitted is used. If the model object does not have a contrast element the user can supply this named list.
	Not used at current.

Details

Computes two decompositions of the model's R2 and returns a matrix of designations from which predictor relative importance determinations can be obtained.

Note in the output that the "constant" subset is associated with a component of the model that does not directly contribute to the R2 such as an intercept. The "all" subset is apportioned a component of the fit statistic but is not considered a part of the dominance analysis and therefore does not receive a rank, conditional dominance statistics, or complete dominance designations.

The input model is parsed using insight::find_predictors(), does not yet support interactions, transformations, or offsets applied in the R formula, and will fail with an error if any such terms are detected.

The model submitted must accept an formula object as a formula argument. In addition, the model object must accept the data on which the model is estimated as a data argument. Formulas submitted using object references (i.e., lm(mtcars\$mpg ~ mtcars\$vs)) and functions that accept data as a non-data argument (e.g., survey::svyglm() uses design) will fail with an error.

Models that return TRUE for the insight::model_info() function's values "is_bayesian", "is_mixed", "is_gam", is_multivariate", "is_zero_inflated", or "is_hurdle" are not supported at current.

When performance::r2() returns multiple values, only the first is used by default.

Value

Object of class "parameters_da".

An object of class "parameters_da" is a list of data. frames composed of the following elements:

General A data.frame which associates dominance statistics with model parameters. The variables in this data.frame include:

Parameter Parameter names.

- General_Dominance Vector of general dominance statistics. The R2 ascribed to variables in the all argument are also reported here though they are not general dominance statistics.
- Percent Vector of general dominance statistics normalized to sum to 1.

Ranks Vector of ranks applied to the general dominance statistics.

- Subset Names of the subset to which the parameter belongs in the dominance analysis. Each other data.frame returned will refer to these subset names.
- Conditional A data.frame of conditional dominance statistics. Each observation represents a subset and each variable represents an the average increment to R2 with a specific number of subsets in the model. NULL if conditional argument is FALSE.
- Complete A data.frame of complete dominance designations. The subsets in the observations are compared to the subsets referenced in each variable. Whether the subset in each variable dominates the subset in each observation is represented in the logical value. NULL if complete argument is FALSE.

equivalence_test.lm Equivalence test

Description

Compute the (conditional) equivalence test for frequentist models.

Usage

```
## S3 method for class 'lm'
equivalence_test(
    x,
    range = "default",
    ci = 0.95,
    rule = "classic",
    verbose = TRUE,
    ...
)
## S3 method for class 'merMod'
equivalence_test(
    x,
    range = "default",
    ci = 0.95,
    rule = "classic",
```

```
effects = c("fixed", "random"),
verbose = TRUE,
...
)
## S3 method for class 'ggeffects'
equivalence_test(
    x,
    range = "default",
    rule = "classic",
    test = "pairwise",
    verbose = TRUE,
    ...
)
```

Arguments

х	A statistical model.
range	The range of practical equivalence of an effect. May be "default", to automat- ically define this range based on properties of the model's data.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
rule	Character, indicating the rules when testing for practical equivalence. Can be "bayes", "classic" or "cet". See 'Details'.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods.
effects	Should parameters for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. If the calculation of random effects parameters takes too long, you may use effects = "fixed".
test	Hypothesis test for computing contrasts or pairwise comparisons. See ?ggeffects::test_predictions for details.

Details

In classical null hypothesis significance testing (NHST) within a frequentist framework, it is not possible to accept the null hypothesis, H0 - unlike in Bayesian statistics, where such probability statements are possible. "... one can only reject the null hypothesis if the test statistics falls into the critical region(s), or fail to reject this hypothesis. In the latter case, all we can say is that no significant effect was observed, but one cannot conclude that the null hypothesis is true." (*Pernet 2017*). One way to address this issues without Bayesian methods is *Equivalence Testing*, as implemented in equivalence_test(). While you either can reject the null hypothesis or claim an inconclusive result in NHST, the equivalence test - according to *Pernet* - adds a third category, "accept". Roughly speaking, the idea behind equivalence interval) falls within a region of "practical equivalence". Depending on the rule for this test (see below), statistical significance does not necessarily indicate whether the null hypothesis can be rejected or not, i.e. the classical interpretation of the p-value may differ from the results returned from the equivalence test.

42

Calculation of equivalence testing:

• "bayes" - Bayesian rule (Kruschke 2018)

This rule follows the "HDI+ROPE decision rule" (*Kruschke*, 2014, 2018) used for the Bayesian counterpart(). This means, if the confidence intervals are completely outside the ROPE, the "null hypothesis" for this parameter is "rejected". If the ROPE completely covers the CI, the null hypothesis is accepted. Else, it's undecided whether to accept or reject the null hypothesis. Desirable results are low proportions inside the ROPE (the closer to zero the better).

• "classic" - The TOST rule (Lakens 2017)

This rule follows the "TOST rule", i.e. a two one-sided test procedure (*Lakens 2017*). Following this rule, practical equivalence of an effect (i.e. H0) is *rejected*, when the coefficient is statistically significant *and* the narrow confidence intervals (i.e. 1-2*alpha) *include* or *exceed* the ROPE boundaries. Practical equivalence is assumed (i.e. H0 "accepted") when the narrow confidence intervals are completely inside the ROPE, no matter if the effect is statistically significant or not. Else, the decision whether to accept or reject practical equivalence is undecided.

• "cet" - Conditional Equivalence Testing (Campbell/Gustafson 2018)

The Conditional Equivalence Testing as described by *Campbell and Gustafson 2018*. According to this rule, practical equivalence is rejected when the coefficient is statistically significant. When the effect is *not* significant and the narrow confidence intervals are completely inside the ROPE, we accept (i.e. assume) practical equivalence, else it is undecided.

Levels of Confidence Intervals used for Equivalence Testing:

For rule = "classic", "narrow" confidence intervals are used for equivalence testing. "Narrow" means, the the intervals is not 1 - alpha, but 1 - 2 * alpha. Thus, if ci = .95, alpha is assumed to be 0.05 and internally a ci-level of 0.90 is used. rule = "cet" uses both regular and narrow confidence intervals, while rule = "bayes" only uses the regular intervals.

p-Values:

The equivalence p-value is the area of the (cumulative) confidence distribution that is outside of the region of equivalence. It can be interpreted as p-value for *rejecting* the alternative hypothesis and *accepting* the "null hypothesis" (i.e. assuming practical equivalence). That is, a high p-value means we reject the assumption of practical equivalence and accept the alternative hypothesis.

Second Generation p-Value (SGPV):

Second generation p-values (SGPV) were proposed as a statistic that represents *the proportion of data-supported hypotheses that are also null hypotheses (Blume et al. 2018, Lakens and Delacre 2020)*. It represents the proportion of the confidence interval range that is inside the ROPE.

ROPE range:

Some attention is required for finding suitable values for the ROPE limits (argument range). See 'Details' in bayestestR::rope_range() for further information.

Value

A data frame.

Note

There is also a plot()-method implemented in the see-package.

factor_analysis Principal Component Analysis (PCA) and Factor Analysis (FA)

Description

The functions principal_components() and factor_analysis() can be used to perform a principal component analysis (PCA) or a factor analysis (FA). They return the loadings as a data frame, and various methods and functions are available to access / display other information (see the Details section).

factor_analysis

Usage

```
factor_analysis(
  х,
  n = "auto",
  rotation = "none",
  sort = FALSE,
  threshold = NULL,
  standardize = TRUE,
  cor = NULL,
  . . .
)
principal_components(
  х,
 n = "auto",
 rotation = "none",
  sparse = FALSE,
  sort = FALSE,
  threshold = NULL,
  standardize = TRUE,
  . . .
)
rotated_data(pca_results, verbose = TRUE)
## S3 method for class 'parameters_efa'
predict(
 object,
 newdata = NULL,
 names = NULL,
 keep_na = TRUE,
 verbose = TRUE,
  . . .
)
## S3 method for class 'parameters_efa'
print(x, digits = 2, sort = FALSE, threshold = NULL, labels = NULL, ...)
## S3 method for class 'parameters_efa'
sort(x, ...)
```

closest_component(pca_results)

Arguments

х	A data frame or a statistical model.
n	Number of components to extract. If n="all", then n is set as the number of
	variables minus 1 (ncol(x)-1). If n="auto" (default) or n=NULL, the number

	of components is selected through n_factors() resp. n_components(). Else, if n is a number, n components are extracted. If n exceeds number of variables in the data, it is automatically set to the maximum number (i.e. ncol(x)). In reduce_parameters(), can also be "max", in which case it will select all the components that are maximally pseudo-loaded (i.e., correlated) by at least one variable.
rotation	If not "none", the PCA / FA will be computed using the psych package. Possible options include "varimax", "quartimax", "promax", "oblimin", "simplimax", or "cluster" (and more). See psych::fa() for details.
sort	Sort the loadings.
threshold	A value between 0 and 1 indicates which (absolute) values from the loadings should be removed. An integer higher than 1 indicates the n strongest loadings to retain. Can also be "max", in which case it will only display the maximum loading per variable (the most simple structure).
standardize	A logical value indicating whether the variables should be standardized (cen- tered and scaled) to have unit variance before the analysis (in general, such scaling is advisable).
cor	An optional correlation matrix that can be used (note that the data must still be passed as the first argument). If NULL, will compute it by running cor() on the passed data.
	Arguments passed to or from other methods.
sparse	Whether to compute sparse PCA (SPCA, using sparsepca::spca()). SPCA attempts to find sparse loadings (with few nonzero values), which improves interpretability and avoids overfitting. Can be TRUE or "robust" (see sparsepca::robspca()).
pca_results	The output of the principal_components() function.
verbose	Toggle warnings.
object	An object of class parameters_pca or parameters_efa
newdata	An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
names	Optional character vector to name columns of the returned data frame.
keep_na	Logical, if TRUE, predictions also return observations with missing values from the original data, hence the number of rows of predicted data and original data is equal.
digits, labels	Arguments for print().

Details

Methods and Utilities:

- n_components() and n_factors() automatically estimates the optimal number of dimensions to retain.
- performance::check_factorstructure() checks the suitability of the data for factor analysis using the sphericity (see performance::check_sphericity_bartlett()) and the KMO (see performance::check_kmo()) measure.

factor_analysis

- performance::check_itemscale() computes various measures of internal consistencies applied to the (sub)scales (i.e., components) extracted from the PCA.
- Running summary() returns information related to each component/factor, such as the explained variance and the Eivenvalues.
- Running get_scores() computes scores for each subscale.
- Running closest_component() will return a numeric vector with the assigned component index for each column from the original data frame.
- Running rotated_data() will return the rotated data, including missing values, so it matches the original data frame.
- Running plot() visually displays the loadings (that requires the see-package to work).

Complexity:

Complexity represents the number of latent components needed to account for the observed variables. Whereas a perfect simple structure solution has a complexity of 1 in that each item would only load on one factor, a solution with evenly distributed items has a complexity greater than 1 (*Hofman, 1978; Pettersson and Turkheimer, 2010*).

Uniqueness:

Uniqueness represents the variance that is 'unique' to the variable and not shared with other variables. It is equal to 1 communality (variance that is shared with other variables). A uniqueness of 0.20 suggests that 20% or that variable's variance is not shared with other variables in the overall factor model. The greater 'uniqueness' the lower the relevance of the variable in the factor model.

MSA:

MSA represents the Kaiser-Meyer-Olkin Measure of Sampling Adequacy (*Kaiser and Rice, 1974*) for each item. It indicates whether there is enough data for each factor give reliable results for the PCA. The value should be > 0.6, and desirable values are > 0.8 (*Tabachnick and Fidell, 2013*).

PCA or FA?:

There is a simplified rule of thumb that may help do decide whether to run a factor analysis or a principal component analysis:

- Run *factor analysis* if you assume or wish to test a theoretical model of *latent factors* causing observed variables.
- Run *principal component analysis* If you want to simply *reduce* your correlated observed variables to a smaller set of important independent composite variables.

(Source: CrossValidated)

Computing Item Scores:

Use get_scores() to compute scores for the "subscales" represented by the extracted principal components. get_scores() takes the results from principal_components() and extracts the variables for each component found by the PCA. Then, for each of these "subscales", raw means are calculated (which equals adding up the single items and dividing by the number of items). This results in a sum score for each component from the PCA, which is on the same scale as the original, single items that were used to compute the PCA. One can also use predict() to back-predict scores for each component, to which one can provide newdata or a vector of names for the components.

Explained Variance and Eingenvalues:

Use summary() to get the Eigenvalues and the explained variance for each extracted component. The eigenvectors and eigenvalues represent the "core" of a PCA: The eigenvectors (the principal components) determine the directions of the new feature space, and the eigenvalues determine their magnitude. In other words, the eigenvalues explain the variance of the data along the new feature axes.

Value

A data frame of loadings.

fish

Sample data set

Description

A sample data set, used in tests and some examples.

format_df_adjust Format the name of the degrees-of-freedom adjustment methods

Description

Format the name of the degrees-of-freedom adjustment methods.

Usage

```
format_df_adjust(
   method,
   approx_string = "-approximated",
   dof_string = " degrees of freedom"
)
```

Arguments

method Name of the method.
approx_string, dof_string
Suffix added to the name of the method in the returned string.

Value

A formatted string.

Examples

library(parameters)

```
format_df_adjust("kenward")
format_df_adjust("kenward", approx_string = "", dof_string = " DoF")
```

format_order Order (first, second, ...) formatting

Description

Format order.

Usage

```
format_order(order, textual = TRUE, ...)
```

Arguments

order	value or vector of orders.
textual	Return number as words. If FALSE, will run insight::format_value().
	Arguments to be passed to insight::format_value() if textual is FALSE

Value

A formatted string.

Examples

```
format_order(2)
format_order(8)
format_order(25, textual = FALSE)
```

50

Description

This functions formats the names of model parameters (coefficients) to make them more humanreadable.

Usage

```
format_parameters(model, ...)
```

```
## Default S3 method:
format_parameters(model, brackets = c("[", "]"), ...)
```

Arguments

model	A statistical model.
	Currently not used.
brackets	A character vector of length two, indicating the opening and closing brackets

Value

A (names) character vector with formatted parameter names. The value names refer to the original names of the coefficients.

Interpretation of Interaction Terms

Note that the *interpretation* of interaction terms depends on many characteristics of the model. The number of parameters, and overall performance of the model, can differ *or not* between a * b a : b, and a / b, suggesting that sometimes interaction terms give different parameterizations of the same model, but other times it gives completely different models (depending on a or b being factors of covariates, included as main effects or not, etc.). Their interpretation depends of the full context of the model, which should not be inferred from the parameters table alone - rather, we recommend to use packages that calculate estimated marginal means or marginal effects, such as **modelbased**, **emmeans**, **ggeffects**, or **marginaleffects**. To raise awareness for this issue, you may use print(..., show_formula=TRUE) to add the model-specification to the output of the print() method for model_parameters().

Examples

```
model <- lm(Sepal.Length ~ Species * Sepal.Width, data = iris)
format_parameters(model)
model <- lm(Sepal.Length ~ Petal.Length + (Species / Sepal.Width), data = iris)
format_parameters(model)</pre>
```

```
model <- lm(Sepal.Length ~ Species + poly(Sepal.Width, 2), data = iris)
format_parameters(model)
model <- lm(Sepal.Length ~ Species + poly(Sepal.Width, 2, raw = TRUE), data = iris)
format_parameters(model)</pre>
```

format_p_adjust Format the name of the p-value adjustment methods

Description

Format the name of the p-value adjustment methods.

Usage

format_p_adjust(method)

Arguments

method Name of the method.

Value

A string with the full surname(s) of the author(s), including year of publication, for the adjustmentmethod.

Examples

```
library(parameters)
```

```
format_p_adjust("holm")
format_p_adjust("bonferroni")
```

get_scores

Get Scores from Principal Component Analysis (PCA)

Description

get_scores() takes n_i tems amount of items that load the most (either by loading cutoff or number) on a component, and then computes their average.

Usage

get_scores(x, n_items = NULL)

52

Arguments

х	An object returned by principal_components().
n_items	Number of required (i.e. non-missing) items to build the sum score. If NULL, the
	value is chosen to match half of the number of columns in a data frame

Details

get_scores() takes the results from principal_components() and extracts the variables for each component found by the PCA. Then, for each of these "subscales", row means are calculated (which equals adding up the single items and dividing by the number of items). This results in a sum score for each component from the PCA, which is on the same scale as the original, single items that were used to compute the PCA.

Value

A data frame with subscales, which are average sum scores for all items from each component.

Examples

```
if (require("psych")) {
  pca <- principal_components(mtcars[, 1:7], n = 2, rotation = "varimax")
  # PCA extracted two components
  pca
  # assignment of items to each component
  closest_component(pca)
  # now we want to have sum scores for each component
  get_scores(pca)
  # compare to manually computed sum score for 2nd component, which
  # consists of items "hp" and "qsec"
  (mtcars$hp + mtcars$qsec) / 2
}</pre>
```

model_parameters Model Parameters

Description

Compute and extract model parameters. The available options and arguments depend on the modeling **package** and model class. Follow one of these links to read the model-specific documentation:

- Default method: 1m, g1m, stats, censReg, MASS, survey, ...
- Additive models: bamlss, gamlss, mgcv, scam, VGAM, Gam, gamm, ...
- ANOVA: afex, aov, anova, ...

- Bayesian: BayesFactor, blavaan, brms, MCMCglmm, posterior, rstanarm, bayesQR, bcplm, BGGM, blmrm, blrm, mcmc.list, MCMCglmm, ...
- Clustering: hclust, kmeans, mclust, pam, ...
- Correlations, t-tests, etc.: Imtest, htest, pairwise.htest, ...
- Meta-Analysis: metaBMA, metafor, metaplus, ...
- Mixed models: cplm, glmmTMB, lme4, lmerTest, nlme, ordinal, robustlmm, spaMM, mixed, MixMod, ...
- Multinomial, ordinal and cumulative link: brglm2, DirichletReg, nnet, ordinal, mlm, ...
- Multiple imputation: mice
- PCA, FA, CFA, SEM: FactoMineR, lavaan, psych, sem, ...
- Zero-inflated and hurdle: cplm, mhurdle, pscl, ...
- Other models: aod, bbmle, betareg, emmeans, epiR, ggeffects, glmx, ivfixed, ivprobit, JRM, Imodel2, logitsf, marginaleffects, margins, maxLik, mediation, mfx, multcomp, mvord, plm, PMCMRplus, quantreg, selection, systemfit, tidymodels, varEST, WRS2, bfsl, deltaMethod, fitdistr, mjoint, mle, model.avg, ...

Usage

```
model_parameters(model, ...)
```

parameters(model, ...)

Arguments

. . .

```
model Statistical Model.
```

Arguments passed to or from other methods. Non-documented arguments are digits, p_digits, ci_digits and footer_digits to set the number of digits for the output. If s_value = TRUE, the p-value will be replaced by the S-value in the output (cf. *Rafi and Greenland 2020*). pd adds an additional column with the *probability of direction* (see bayestestR::p_direction() for details). groups can be used to group coefficients. It will be passed to the print-method, or can directly be used in print(), see documentation in print.parameters_model(). Furthermore, see 'Examples' in model_parameters.default(). For developers, whose interest mainly is to get a "tidy" data frame of model summaries, it is recommended to set pretty_names = FALSE to speed up computation of the summary table.

Value

A data frame of indices related to the model's parameters.

Standardization of model coefficients

Standardization is based on standardize_parameters(). In case of standardize = "refit", the data used to fit the model will be standardized and the model is completely refitted. In such cases, standard errors and confidence intervals refer to the standardized coefficient. The default,

standardize = "refit", never standardizes categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages or other software packages (like SPSS). To mimic behaviour of SPSS or packages such as **lm.beta**, use standardize = "basic".

Standardization Methods

- refit: This method is based on a complete model re-fit with a standardized version of the data. Hence, this method is equal to standardizing the variables before fitting the model. It is the "purest" and the most accurate (Neter et al., 1989), but it is also the most computationally costly and long (especially for heavy models such as Bayesian models). This method is particularly recommended for complex models that include interactions or transformations (e.g., polynomial or spline terms). The robust (default to FALSE) argument enables a robust standardization of data, i.e., based on the median and MAD instead of the mean and SD. See standardize() for more details. Note that standardize_parameters(method = "refit") may not return the same results as fitting a model on data that has been standardized with standardize(); standardize_parameters() used the data used by the model fitting function, which might not be same data if there are missing values. see the remove_na argument in standardize().
- **posthoc**: Post-hoc standardization of the parameters, aiming at emulating the results obtained by "refit" without refitting the model. The coefficients are divided by the standard deviation (or MAD if robust) of the outcome (which becomes their expression 'unit'). Then, the coefficients related to numeric variables are additionally multiplied by the standard deviation (or MAD if robust) of the related terms, so that they correspond to changes of 1 SD of the predictor (e.g., "A change in 1 SD of x is related to a change of 0.24 of the SD of y). This does not apply to binary variables or factors, so the coefficients are still related to changes in levels. This method is not accurate and tend to give aberrant results when interactions are specified.
- **basic**: This method is similar to method = "posthoc", but treats all variables as continuous: it also scales the coefficient by the standard deviation of model's matrix' parameter of factors levels (transformed to integers) or binary predictors. Although being inappropriate for these cases, this method is the one implemented by default in other software packages, such as lm.beta::lm.beta().
- **smart** (Standardization of Model's parameters with Adjustment, Reconnaissance and Transformation *experimental*): Similar to method = "posthoc" in that it does not involve model refitting. The difference is that the SD (or MAD if robust) of the response is computed on the relevant section of the data. For instance, if a factor with 3 levels A (the intercept), B and C is entered as a predictor, the effect corresponding to B vs. A will be scaled by the variance of the response at the intercept only. As a results, the coefficients for effects of factors are similar to a Glass' delta.
- pseudo (for 2-level (G)LMMs only): In this (post-hoc) method, the response and the predictor
 are standardized based on the level of prediction (levels are detected with performance::check_heterogeneity_bias
 Predictors are standardized based on their SD at level of prediction (see also datawizard::demean());
 The outcome (in linear LMMs) is standardized based on a fitted random-intercept-model,
 where sqrt(random-intercept-variance) is used for level 2 predictors, and sqrt(residual-variance)
 is used for level 1 predictors (Hoffman 2015, page 342). A warning is given when a within group variable is found to have access between-group variance.

See also package vignette.

Labeling the Degrees of Freedom

Throughout the **parameters** package, we decided to label the residual degrees of freedom df_error . The reason for this is that these degrees of freedom not always refer to the residuals. For certain models, they refer to the estimate error - in a linear model these are the same, but in - for instance - any mixed effects model, this isn't strictly true. Hence, we think that df_error is the most generic label for these degrees of freedom.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

• Applies to *non-Bayesian models*. For *linear models*, CIs computed using the Wald method (SE and a *t-distribution with residual df*); p-values computed using the Wald method with a *t-distribution with residual df*. For other models, CIs computed using the Wald method (SE and a *normal distribution*); p-values computed using the Wald method with a *normal distribution*.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

model_parameters

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

"ml1"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t*-distribution with *m*-*l*-1 approximated df); p-values computed using the Wald method with a *t*-distribution with *m*-*l*-1 approximated df. See ci_ml1().

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

"uniroot"

• Applies to *non-Bayesian models* of class glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

57

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

 Applies to Bayesian models with proper priors. CIs computed as support intervals comparing the posterior samples against the prior samples; p-values are based on the probability of direction. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

Interpretation of Interaction Terms

Note that the *interpretation* of interaction terms depends on many characteristics of the model. The number of parameters, and overall performance of the model, can differ *or not* between a * b a : b, and a / b, suggesting that sometimes interaction terms give different parameterizations of the same model, but other times it gives completely different models (depending on a or b being factors of covariates, included as main effects or not, etc.). Their interpretation depends of the full context of the model, which should not be inferred from the parameters table alone - rather, we recommend to use packages that calculate estimated marginal means or marginal effects, such as **modelbased**, **emmeans**, **ggeffects**, or **marginaleffects**. To raise awareness for this issue, you may use print(..., show_formula=TRUE) to add the model-specification to the output of the print() method for model_parameters().

Global Options to Customize Messages and Tables when Printing

The verbose argument can be used to display or silence messages and warnings for the different functions in the **parameters** package. However, some messages providing additional information can be displayed or suppressed using options():

- parameters_summary: options(parameters_summary = TRUE) will override the summary argument in model_parameters() and always show the model summary for non-mixed models.
- parameters_mixed_summary: options(parameters_mixed_summary = TRUE) will override the summary argument in model_parameters() for mixed models, and will then always show the model summary.

- parameters_cimethod: options(parameters_cimethod = TRUE) will show the additional information about the approximation method used to calculate confidence intervals and pvalues. Set to FALSE to hide this message when printing model_parameters() objects.
- parameters_exponentiate: options(parameters_exponentiate = TRUE) will show the
 additional information on how to interpret coefficients of models with log-transformed response variables or with log-/logit-links when the exponentiate argument in model_parameters()
 is not TRUE. Set this option to FALSE to hide this message when printing model_parameters()
 objects.

There are further options that can be used to modify the default behaviour for printed outputs:

- parameters_labels: options(parameters_labels = TRUE) will use variable and value labels for pretty names, if data is labelled. If no labels available, default pretty names are used.
- parameters_interaction: options(parameters_interaction = <character>) will replace the interaction mark (by default, *) with the related character.
- parameters_select: options(parameters_select = <value>) will set the default for the select argument. See argument's documentation for available options.
- easystats_html_engine: options(easystats_html_engine = "gt") will set the default HTML engine for tables to gt, i.e. the *gt* package is used to create HTML tables. If set to tt, the *tinytable* package is used.

Note

The print() method has several arguments to tweak the output. There is also a plot()-method implemented in the see-package, and a dedicated method for use inside rmarkdown files, print_md().

For developers, if speed performance is an issue, you can use the (undocumented) pretty_names argument, e.g. model_parameters(..., pretty_names = FALSE). This will skip the formatting of the coefficient names and make model_parameters() faster.

model_parameters.aov Parameters from ANOVAs

Description

Parameters from ANOVAs

Usage

```
## S3 method for class 'aov'
model_parameters(
  model,
  type = NULL,
  df_error = NULL,
  ci = NULL,
  alternative = NULL,
  test = NULL,
  power = FALSE,
  effectsize_type = NULL,
  keep = NULL,
  drop = NULL,
  table_wide = FALSE,
  verbose = TRUE,
  omega_squared = NULL,
  eta_squared = NULL,
  epsilon_squared = NULL,
  . . .
)
## S3 method for class 'afex_aov'
model_parameters(
 model,
  effectsize_type = NULL,
  df_error = NULL,
  type = NULL,
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
)
```

Arguments

model Object of class aov(), anova(), aovlist, Gam, manova(), Anova.mlm, afex_aov or maov. type Numeric, type of sums of squares. May be 1, 2 or 3. If 2 or 3, ANOVA-tables using car::Anova() will be returned. (Ignored for afex_aov.)

df_error	Denominator degrees of freedom (or degrees of freedom of the error estimate, i.e., the residuals). This is used to compute effect sizes for ANOVA-tables from mixed models. See 'Examples'. (Ignored for afex_aov.)
ci	Confidence Interval (CI) level for effect sizes specified in effectsize_type. The default, NULL, will compute no confidence intervals. ci should be a scalar between 0 and 1.
alternative	A character string specifying the alternative hypothesis; Controls the type of CI returned: "two.sided" (default, two-sided CI), "greater" or "less" (one-sided CI). Partial matching is allowed (e.g., "g", "l", "two"). See section <i>One-Sided CIs</i> in the effectsize_CIs vignette.
test	String, indicating the type of test for Anova.mlm to be returned. If "multivariate" (or NULL), returns the summary of the multivariate test (that is also given by the print-method). If test = "univariate", returns the summary of the univariate test.
power	Logical, if TRUE, adds a column with power for each parameter.
effectsize_type	
	The effect size of interest. Not that possibly not all effect sizes are applicable to the model object. See 'Details'. For Anova models, can also be a character vector with multiple effect size names.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the <i>"Parameter"</i> column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
table_wide	Logical that decides whether the ANOVA table should be in wide format, i.e. should the numerator and denominator degrees of freedom be in the same row. Default: FALSE.
verbose	Toggle warnings and messages.
omega_squared,	eta_squared, epsilon_squared
	Argumente messed te effecteize effecteize (). Er mensele te el
	late <i>partial</i> effect sizes types, use partial = TRUE. For objects of class htest or BFBayesFactor, adjust = TRUE can be used to return bias-corrected effect

model_parameters.aov

sizes, which is advisable for small samples and large tables. See also ?effectsize::eta_squared for arguments partial and generalized; ?effectsize::phi for adjust; and ?effectsize::oddratio for log.

Details

- For an object of class htest, data is extracted via insight::get_data(), and passed to the relevant function according to:
 - A **t-test** depending on type: "cohens_d" (default), "hedges_g", or one of "p_superiority", "u1", "u2", "u3", "overlap".
 - * For a **Paired t-test**: depending on type: "rm_rm", "rm_av", "rm_b", "rm_d", "rm_z".
 - A Chi-squared tests of independence or Fisher's Exact Test, depending on type: "cramers_v" (default), "tschuprows_t", "phi", "cohens_w", "pearsons_c", "cohens_h", "oddsratio", "riskratio", "arr", or "nnt".
 - A Chi-squared tests of goodness-of-fit, depending on type: "fei" (default) "cohens_w", "pearsons_c"
 - A One-way ANOVA test, depending on type: "eta" (default), "omega" or "epsilon" -squared, "f", or "f2".
 - A McNemar test returns Cohen's g.
 - A Wilcoxon test depending on type: returns "rank_biserial" correlation (default) or one of "p_superiority", "vda", "u2", "u3", "overlap".
 - A Kruskal-Wallis test depending on type: "epsilon" (default) or "eta".
 - A **Friedman test** returns *Kendall's W*. (Where applicable, ci and alternative are taken from the htest if not otherwise provided.)
- For an object of class BFBayesFactor, using bayestestR::describe_posterior(),
 - A t-test depending on type: "cohens_d" (default) or one of "p_superiority", "u1", "u2", "u3", "overlap".
 - A correlation test returns r.
 - A contingency table test, depending on type: "cramers_v" (default), "phi", "tschuprows_t", "cohens_w", "pearsons_c", "cohens_h", "oddsratio", or "riskratio", "arr", or "nnt".
 - A proportion test returns *p*.
- Objects of class anova, aov, aovlist or afex_aov, depending on type: "eta" (default), "omega" or "epsilon" -squared, "f", or "f2".
- Other objects are passed to parameters::standardize_parameters().

For statistical models it is recommended to directly use the listed functions, for the full range of options they provide.

Value

A data frame of indices related to the model's parameters.

Note

For ANOVA-tables from mixed models (i.e. anova(lmer())), only partial or adjusted effect sizes can be computed. Note that type 3 ANOVAs with interactions involved only give sensible and informative results when covariates are mean-centred and factors are coded with orthogonal contrasts (such as those produced by contr.sum, contr.poly, or contr.helmert, but *not* by the default contr.treatment).

Examples

```
df <- iris
df$Sepal.Big <- ifelse(df$Sepal.Width >= 3, "Yes", "No")
model <- aov(Sepal.Length ~ Sepal.Big, data = df)</pre>
model_parameters(model)
model_parameters(model, effectsize_type = c("omega", "eta"), ci = 0.9)
model <- anova(lm(Sepal.Length ~ Sepal.Big, data = df))</pre>
model_parameters(model)
model_parameters(
  model,
  effectsize_type = c("omega", "eta", "epsilon"),
  alternative = "greater"
)
model <- aov(Sepal.Length ~ Sepal.Big + Error(Species), data = df)</pre>
model_parameters(model)
df <- iris
df$Sepal.Big <- ifelse(df$Sepal.Width >= 3, "Yes", "No")
mm <- lme4::lmer(Sepal.Length ~ Sepal.Big + Petal.Width + (1 | Species), data = df)</pre>
model <- anova(mm)</pre>
# simple parameters table
model_parameters(model)
# parameters table including effect sizes
model_parameters(
  model,
  effectsize_type = "eta",
  ci = 0.9,
  df_error = dof_satterthwaite(mm)[2:3]
)
```

model_parameters.befa Parameters from Bayesian Exploratory Factor Analysis

Description

Format Bayesian Exploratory Factor Analysis objects from the BayesFM package.

Usage

```
## S3 method for class 'befa'
model_parameters(
   model,
   sort = FALSE,
   centrality = "median",
   dispersion = FALSE,
   ci = 0.95,
   ci_method = "eti",
   test = NULL,
   verbose = TRUE,
   ...
)
```

Arguments

model	Bayesian EFA created by the BayesFM::befa.
sort	Sort the loadings.
centrality	The point-estimates (centrality indices) to compute. Character (vector) or list with one or more of these options: "median", "mean", "MAP" (see map_estimate()), "trimmed" (which is just mean(x, trim = threshold)), "mode" or "all".
dispersion	Logical, if TRUE, computes indices of dispersion related to the estimate(s) (SD and MAD for mean and median, respectively). Dispersion is not available for "MAP" or "mode" centrality indices.
ci	Value or vector of probability of the CI (between 0 and 1) to be estimated. Default to 0.95 (95%).
ci_method	The type of index used for Credible Interval. Can be "ETI" (default, see eti()), "HDI" (see hdi()), "BCI" (see bci()), "SPI" (see spi()), or "SI" (see si()).
test	The indices of effect existence to compute. Character (vector) or list with one or more of these options: "p_direction" (or "pd"), "rope", "p_map", "equivalence_test" (or "equitest"), "bayesfactor" (or "bf") or "all" to compute all tests. For each "test", the corresponding bayestestR function is called (e.g. rope() or p_direction()) and its results included in the summary output.
verbose	Toggle warnings.
	Arguments passed to or from other methods.

Value

A data frame of loadings.

Examples

library(parameters)

```
if (require("BayesFM")) {
    efa <- BayesFM::befa(mtcars, iter = 1000)
    results <- model_parameters(efa, sort = TRUE, verbose = FALSE)
    results
    efa_to_cfa(results, verbose = FALSE)
}</pre>
```

model_parameters.BFBayesFactor

Parameters from BayesFactor objects

Description

Parameters from BFBayesFactor objects from {BayesFactor} package.

Usage

```
## S3 method for class 'BFBayesFactor'
model_parameters(
 model,
  centrality = "median",
  dispersion = FALSE,
  ci = 0.95,
  ci_method = "eti",
  test = "pd",
  rope_range = "default",
  rope_ci = 0.95,
  priors = TRUE,
  effectsize_type = NULL,
  include_proportions = FALSE,
  verbose = TRUE,
  cohens_d = NULL,
  cramers_v = NULL,
  . . .
)
```

Arguments

model	Object of class BFBayesFactor.
centrality	The point-estimates (centrality indices) to compute. Character (vector) or list with one or more of these options: "median", "mean", "MAP" (see map_estimate()), "trimmed" (which is just mean(x, trim = threshold)), "mode" or "all".
dispersion	Logical, if TRUE, computes indices of dispersion related to the estimate(s) (SD and MAD for mean and median, respectively). Dispersion is not available for "MAP" or "mode" centrality indices.
ci	Value or vector of probability of the CI (between 0 and 1) to be estimated. Default to 0.95 (95%).
ci_method	The type of index used for Credible Interval. Can be "ETI" (default, see eti()), "HDI" (see hdi()), "BCI" (see bci()), "SPI" (see spi()), or "SI" (see si()).
test	The indices of effect existence to compute. Character (vector) or list with one or more of these options: "p_direction" (or "pd"), "rope", "p_map", "equivalence_test" (or "equitest"), "bayesfactor" (or "bf") or "all" to compute all tests. For each "test", the corresponding bayestestR function is called (e.g. rope() or p_direction()) and its results included in the summary output.
rope_range	ROPE's lower and higher bounds. Should be a list of two values (e.g., c(-0.1, 0.1)) or "default". If "default", the bounds are set to x +- 0.1*SD(response).
rope_ci	The Credible Interval (CI) probability, corresponding to the proportion of HDI, to use for the percentage in ROPE.
priors	Add the prior used for each parameter.
effectsize_type	e
	The effect size of interest. Not that possibly not all effect sizes are applicable to the model object. See 'Details'. For Anova models, can also be a character vector with multiple effect size names.
include_proport	tions
	Logical that decides whether to include posterior cell proportions/counts for Bayesian contingency table analysis (from BayesFactor::contingencyTableBF()). Defaults to FALSE, as this information is often redundant.
verbose	Toggle off warnings.
cohens_d, crame	rs_v
	Deprecated. Please use effectsize_type.
	Additional arguments to be passed to or from methods.

Details

The meaning of the extracted parameters:

- For BayesFactor::ttestBF(): Difference is the raw difference between the means.
- For BayesFactor::correlationBF(): rho is the linear correlation estimate (equivalent to Pearson's *r*).
- For BayesFactor:: ImBF() / BayesFactor:: generalTestBF() / BayesFactor:: regressionBF() / BayesFactor:: anovaBF(): in addition to parameters of the fixed and random effects, there are: mu is the (mean-centered) intercept; sig2 is the model's sigma; g / g_* are the g parameters; See the *Bayes Factors for ANOVAs* paper (doi:10.1016/j.jmp.2012.08.001).

Value

A data frame of indices related to the model's parameters.

Examples

```
if (require("BayesFactor")) {
 # Bayesian t-test
 model <- ttestBF(x = rnorm(100, 1, 1))
 model_parameters(model)
 model_parameters(model, cohens_d = TRUE, ci = .9)
 # Bayesian contingency table analysis
 data(raceDolls)
 bf <- contingencyTableBF(raceDolls, sampleType = "indepMulti", fixedMargin = "cols")</pre>
 model_parameters(bf,
   centrality = "mean",
   dispersion = TRUE,
   verbose = FALSE,
   effectsize_type = "cramers_v"
 )
}
```

model_parameters.cgam Parameters from Generalized Additive (Mixed) Models

Description

Extract and compute indices and measures to describe parameters of generalized additive models (GAM(M)s).

Usage

```
## S3 method for class 'cgam'
model_parameters(
 model,
  ci = 0.95,
  ci_method = "residual",
  bootstrap = FALSE,
  iterations = 1000,
  standardize = NULL,
  exponentiate = FALSE,
  p_adjust = NULL,
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
  . . .
```

```
)
## S3 method for class 'gamm'
model_parameters(
 model,
 ci = 0.95,
 bootstrap = FALSE,
  iterations = 1000,
 verbose = TRUE,
  . . .
)
## S3 method for class 'Gam'
model_parameters(
 model,
  effectsize_type = NULL,
 df_error = NULL,
  type = NULL,
  table_wide = FALSE,
  verbose = TRUE,
  . . .
)
## S3 method for class 'scam'
model_parameters(
 model,
 ci = 0.95,
  ci_method = "residual",
 bootstrap = FALSE,
  iterations = 1000,
  standardize = NULL,
  exponentiate = FALSE,
  p_adjust = NULL,
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
  . . .
)
```

Arguments

model	A gam/gamm model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
ci_method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi</i> -

68

	<i>dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized.
	 Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
p_adjust	Character vector, if not NULL, indicates the method to adjust p-values. See <pre>stats::p.adjust()</pre> for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, ev- ery parameter name in the <i>"Parameter"</i> column that matches the regular ex- pression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: <i>"</i> (one two three) <i>"</i> . If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter

	components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().
effectsize_type	
	The effect size of interest. Not that possibly not all effect sizes are applicable to the model object. See 'Details'. For Anova models, can also be a character vector with multiple effect size names.
df_error	Denominator degrees of freedom (or degrees of freedom of the error estimate, i.e., the residuals). This is used to compute effect sizes for ANOVA-tables from mixed models. See 'Examples'. (Ignored for afex_aov.)
type	Numeric, type of sums of squares. May be 1, 2 or 3. If 2 or 3, ANOVA-tables using car::Anova() will be returned. (Ignored for afex_aov.)
table_wide	Logical that decides whether the ANOVA table should be in wide format, i.e. should the numerator and denominator degrees of freedom be in the same row. Default: FALSE.

Details

The reporting of degrees of freedom *for the spline terms* slightly differs from the output of summary(model), for example in the case of mgcv::gam(). The *estimated degrees of freedom*, column edf in the summary-output, is named df in the returned data frame, while the column df_error in the returned data frame refers to the residual degrees of freedom that are returned by df.residual(). Hence, the values in the the column df_error differ from the column Ref.df from the summary, which is intentional, as these reference degrees of freedom "is not very interpretable" (web).

Value

A data frame of indices related to the model's parameters.

See Also

insight::standardize_names() to rename columns into a consistent, standardized naming scheme.

Examples

```
library(parameters)
if (require("mgcv")) {
  dat <- gamSim(1, n = 400, dist = "normal", scale = 2)
  model <- gam(y ~ s(x0) + s(x1) + s(x2) + s(x3), data = dat)
  model_parameters(model)
}</pre>
```

model_parameters.cpglmm

Parameters from Mixed Models

Description

Parameters from (linear) mixed models.

Usage

```
## S3 method for class 'cpglmm'

model	A mixed model.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
ci_method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite",

	<pre>"kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section Confi- dence intervals and approximation of degrees of freedom in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.</pre>
ci_random	Logical, if TRUE, includes the confidence intervals for random effects parame- ters. Only applies if effects is not "fixed" and if ci is not NULL. Set ci_random = FALSE if computation of the model summary is too much time consuming. By default, ci_random = NULL, which uses a heuristic to guess if computation of confidence intervals for random effects is fast enough or not. For models with larger sample size and/or more complex random effects structures, confidence intervals will not be computed by default, for simpler models or fewer observa- tions, confidence intervals will be included. Set explicitly to TRUE or FALSE to enforce or omit calculation of confidence intervals.
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of draws to simulate/bootstrap.
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized. Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
effects	Should parameters for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. If the calculation of random effects parameters takes too long, you may use effects = "fixed".
group_level	Logical, for multilevel models (i.e. models with random effects) and when effects = "all" or effects = "random", include the parameters for each group level from random effects. If group_level = FALSE (the default), only informa- tion on SD and COR are shown.
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate

= "nongaussian" will only exponentiate coefficients from non-Gaussian families.

p_adjust Character vector, if not NULL, indicates the method to adjust p-values. See stats::p.adjust() for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).

include_sigma Logical, if TRUE, includes the residual standard deviation. For mixed models, this is defined as the sum of the distribution-specific variance and the variance for the additive overdispersion term (see insight::get_variance() for details). Defaults to FALSE for mixed models due to the longer computation time.

Character containing a regular expression pattern that describes the parameters keep that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the "Parameter" column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.

drop See keep.

verbose Toggle warnings and messages.

... Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().

component Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.

wb_component Logical, if TRUE and models contains within- and between-effects (see datawizard::demean()), the Component column will indicate which variables belong to the within-effects, between-effects, and cross-level interactions. By default, the Component column indicates, which parameters belong to the conditional or zero-inflation component of the model.

summary Logical, if TRUE, prints summary information about the model (model formula, number of observations, residual standard deviation and more).

vcov Variance-covariance matrix used to compute uncertainty estimates (e.g., for robust standard errors). This argument accepts a covariance matrix, a function which returns a covariance matrix, or a string which identifies the function to be used to compute the covariance matrix.

- A covariance matrix
- A function which returns a covariance matrix (e.g., stats::vcov())
- A string which indicates the kind of uncertainty estimates to return.
 - Heteroskedasticity-consistent: "vcovHC", "HC", "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". See ?sandwich::vcovHC.
 - Cluster-robust: "vcovCR", "CR0", "CR1", "CR1p", "CR1S", "CR2", "CR3". See ?clubSandwich::vcovCR.
 - Bootstrap: "vcovBS", "xy", "residual", "wild", "mammen", "webb".
 See ?sandwich::vcovBS.
 - Other sandwich package functions: "vcovHAC", "vcovPC", "vcovCL", "vcovPL".
- vcov_argsList of arguments to be passed to the function identified by the vcov argument.
This function is typically supplied by the **sandwich** or **clubSandwich** packages.
Please refer to their documentation (e.g., ?sandwich::vcovHAC) to see the list
of available arguments.

Value

A data frame of indices related to the model's parameters.

Confidence intervals for random effects variances

For models of class merMod and glmmTMB, confidence intervals for random effect variances can be calculated.

- For models of from package **lme4**, when ci_method is either "profile" or "boot", and effects is either "random" or "all", profiled resp. bootstrapped confidence intervals are computed for the random effects.
- For all other options of ci_method, and only when the **merDeriv** package is installed, confidence intervals for random effects are based on normal-distribution approximation, using the delta-method to transform standard errors for constructing the intervals around the log-transformed SD parameters. These are than back-transformed, so that random effect variances, standard errors and confidence intervals are shown on the original scale. Due to the transformation, the intervals are asymmetrical, however, they are within the correct bounds (i.e. no negative interval for the SD, and the interval for the correlations is within the range from -1 to +1).
- For models of class glmmTMB, confidence intervals for random effect variances always use a Wald t-distribution approximation.

Singular fits (random effects variances near zero)

If a model is "singular", this means that some dimensions of the variance-covariance matrix have been estimated as exactly zero. This often occurs for mixed models with complex random effects structures.

There is no gold-standard about how to deal with singularity and which random-effects specification to choose. One way is to fully go Bayesian (with informative priors). Other proposals are listed in the documentation of performance::check_singularity(). However, since version 1.1.9, the

glmmTMB package allows to use priors in a frequentist framework, too. One recommendation is to use a Gamma prior (*Chung et al. 2013*). The mean may vary from 1 to very large values (like 1e8), and the shape parameter should be set to a value of 2.5. You can then update() your model with the specified prior. In **glmmTMB**, the code would look like this:

```
# "model" is an object of class gmmmTMB
prior <- data.frame(
    prior = "gamma(1, 2.5)", # mean can be 1, but even 1e8
    class = "ranef" # for random effects
)
model_with_priors <- update(model, priors = prior)</pre>
```

Large values for the mean parameter of the Gamma prior have no large impact on the random effects variances in terms of a "bias". Thus, if 1 doesn't fix the singular fit, you can safely try larger values.

Dispersion parameters in glmmTMB

For some models from package **glmmTMB**, both the dispersion parameter and the residual variance from the random effects parameters are shown. Usually, these are the same but presented on different scales, e.g.

```
model <- glmmTMB(Sepal.Width ~ Petal.Length + (1|Species), data = iris)
exp(fixef(model)$disp) # 0.09902987
sigma(model)^2 # 0.09902987</pre>
```

For models where the dispersion parameter and the residual variance are the same, only the residual variance is shown in the output.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

 Applies to non-Bayesian models. For linear models, CIs computed using the Wald method (SE and a t-distribution with residual df); p-values computed using the Wald method with a tdistribution with residual df. For other models, CIs computed using the Wald method (SE and a normal distribution); p-values computed using the Wald method with a normal distribution.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

"ml1"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with m-l-1 approximated df*); p-values computed using the Wald method with a *t-distribution with m-l-1 approximated df*. See ci_ml1().

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

"uniroot"

 Applies to non-Bayesian models of class glmmTMB. CIs computed by profiling the likelihood curve for a parameter, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a normal-distribution (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

• Applies to *all models* (*including Bayesian models*). For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

"hdi"

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

 Applies to *Bayesian models* with proper priors. CIs computed as *support intervals* comparing the posterior samples against the prior samples; p-values are based on the *probability of direction*. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

Note

If the calculation of random effects parameters takes too long, you may use effects = "fixed". There is also a plot()-method implemented in the see-package.

model_parameters(model, verbose = TRUE, ...)
```

model	Model object.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
ci_method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi- dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized. Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard

errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.

p_adjust Character vector, if not NULL, indicates the method to adjust p-values. See stats::p.adjust() for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).

summary Logical, if TRUE, prints summary information about the model (model formula, number of observations, residual standard deviation and more).

- keep Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the "Parameter" column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
- drop See keep.

verbose Toggle warnings and messages.

vcov

Toggle warnings and messages.

Variance-covariance matrix used to compute uncertainty estimates (e.g., for robust standard errors). This argument accepts a covariance matrix, a function which returns a covariance matrix, or a string which identifies the function to be used to compute the covariance matrix.

- A covariance matrix
- A function which returns a covariance matrix (e.g., stats::vcov())
- A string which indicates the kind of uncertainty estimates to return.
 - Heteroskedasticity-consistent: "vcovHC", "HC", "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". See ?sandwich::vcovHC.
 - Cluster-robust: "vcovCR", "CR0", "CR1", "CR1p", "CR1S", "CR2", "CR3". See ?clubSandwich::vcovCR.
 - Bootstrap: "vcovBS", "xy", "residual", "wild", "mammen", "webb".
 See ?sandwich::vcovBS.
 - Other sandwich package functions: "vcovHAC", "vcovPC", "vcovCL", "vcovPL".

vcov_args	List of arguments to be passed to the function identified by the vcov argument.
	This function is typically supplied by the sandwich or clubSandwich packages.
	Please refer to their documentation (e.g., ?sandwich::vcovHAC) to see the list
	of available arguments.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().

Value

A data frame of indices related to the model's parameters.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

• Applies to *non-Bayesian models*. For *linear models*, CIs computed using the Wald method (SE and a *t-distribution with residual df*); p-values computed using the Wald method with a *t-distribution with residual df*. For other models, CIs computed using the Wald method (SE and a *normal distribution*); p-values computed using the Wald method with a *normal distribution*.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

"ml1"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t*-distribution with *m*-*l*-1 approximated df); p-values computed using the Wald method with a *t*-distribution with *m*-*l*-1 approximated df. See ci_ml1().

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

"uniroot"

• Applies to *non-Bayesian models* of class glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

• Applies to *all models* (*including Bayesian models*). For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

• Applies to *Bayesian models* with proper priors. CIs computed as *support intervals* comparing the posterior samples against the prior samples; p-values are based on the *probability of direction*. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

model	A model with multinomial or categorical response value.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.
component	Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized. Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
p_adjust	Character vector, if not NULL, indicates the method to adjust p-values. See <pre>stats::p.adjust()</pre> for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).

keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the <i>"Parameter"</i> column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().
summary	Logical, if TRUE, prints summary information about the model (model formula, number of observations, residual standard deviation and more).
νςον	Variance-covariance matrix used to compute uncertainty estimates (e.g., for ro- bust standard errors). This argument accepts a covariance matrix, a function which returns a covariance matrix, or a string which identifies the function to be used to compute the covariance matrix.
	A covariance matrix
	• A function which returns a covariance matrix (e.g., stats::vcov())
	• A string which indicates the kind of uncertainty estimates to return.
	 Heteroskedasticity-consistent: "vcovHC", "HC", "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". See ?sandwich::vcovHC.
	 Cluster-robust: "vcovCR", "CR0", "CR1", "CR1p", "CR1S", "CR2", "CR3". See ?clubSandwich::vcovCR.
	 Bootstrap: "vcovBS", "xy", "residual", "wild", "mammen", "webb". See ?sandwich::vcovBS.
	 Other sandwich package functions: "vcovHAC", "vcovPC", "vcovCL", "vcovPL".
vcov_args	List of arguments to be passed to the function identified by the vcov argument. This function is typically supplied by the sandwich or clubSandwich packages. Please refer to their documentation (e.g., ?sandwich::vcovHAC) to see the list of available arguments.

Details

Multinomial or cumulative link models, i.e. models where the response value (dependent variable) is categorical and has more than two levels, usually return coefficients for each response level.

model_parameters.glht

Hence, the output from model_parameters() will split the coefficient tables by the different levels of the model's response.

Value

A data frame of indices related to the model's parameters.

See Also

insight::standardize_names() to rename columns into a consistent, standardized naming scheme.

```
data("stemcell", package = "brglm2")
model <- brglm2::bracl(
   research ~ as.numeric(religion) + gender,
   weights = frequency,
   data = stemcell,
   type = "ML"
)
model_parameters(model)</pre>
```

model_parameters.glht Parameters from Hypothesis Testing

Description

Parameters from Hypothesis Testing.

```
## S3 method for class 'glht'
model_parameters(
   model,
   ci = 0.95,
   exponentiate = FALSE,
   keep = NULL,
   drop = NULL,
   verbose = TRUE,
   ...
)
```

model	Object of class multcomp::glht() (multcomp) or of class PMCMR, trendPMCMR or osrt (PMCMRplus).
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the " <i>Parameter</i> " column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().

Value

A data frame of indices related to the model's parameters.

Examples

```
if (require("multcomp", quietly = TRUE)) {
    # multiple linear model, swiss data
    lmod <- lm(Fertility ~ ., data = swiss)
    mod <- glht(</pre>
```

```
model = lmod,
   linfct = c(
      "Agriculture = 0",
      "Examination = 0",
      "Education = 0",
      "Catholic = 0",
      "Infant.Mortality = 0"
   )
 )
 model_parameters(mod)
}
if (require("PMCMRplus", quietly = TRUE)) {
 model <- suppressWarnings(</pre>
    kwAllPairsConoverTest(count ~ spray, data = InsectSprays)
 )
 model_parameters(model)
}
```

model_parameters.glimML

Parameters from special models

Description

Parameters from special regression models not listed under one of the previous categories yet.

```

)
```

model	Model object.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.
component	Model component for which parameters should be shown. May be one of "conditional", "precision" (betareg), "scale" (ordinal), "extra" (glmx), "marginal" (mfx), "conditional" or "full" (for MuMIn::model.avg()) or "all".
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	• The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as lm.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model.

- For mixed models, when using methods other than "refit", only the fixed effects will be standardized.
- Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
- exponentiate Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
- p_adjust Character vector, if not NULL, indicates the method to adjust p-values. See stats::p.adjust() for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).
- summary Logical, if TRUE, prints summary information about the model (model formula, number of observations, residual standard deviation and more).
- Character containing a regular expression pattern that describes the parameters keep that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the "Parameter" column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names. drop See keep.
- verbose Toggle warnings and messages.
- ... Arguments passed to or from other methods. For instance, when bootstrap =
- TRUE, arguments like type or parallel are passed down to bootstrap_model(). include_studies
 - Logical, if TRUE (default), includes parameters for all studies. Else, only parameters for overall-effects are shown.
- ci_method Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on

	the model class): "residual", "normal", "likelihood", "satterthwaite",
	"kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin",
	"hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section Confi-
	<i>dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.
effects	Should results for fixed effects, random effects or both be returned? Only applies to mixed models. May be abbreviated.

Value

A data frame of indices related to the model's parameters.

See Also

insight::standardize_names() to rename columns into a consistent, standardized naming scheme.

Examples

```
library(parameters)
if (require("brglm2", quietly = TRUE)) {
  data("stemcell")
  model <- bracl(
    research ~ as.numeric(religion) + gender,
    weights = frequency,
    data = stemcell,
    type = "ML"
    )
    model_parameters(model)
}</pre>
```

model_parameters.htest

Parameters from hypothesis tests

Description

Parameters of h-tests (correlations, t-tests, chi-squared, ...).

```
## S3 method for class 'htest'
model_parameters(
   model,
   ci = 0.95,
   alternative = NULL,
   bootstrap = FALSE,
   effectsize_type = NULL,
   verbose = TRUE,
```

```
cramers_v = NULL,
  phi = NULL,
  standardized_d = NULL,
  hedges_g = NULL,
  omega_squared = NULL,
  eta_squared = NULL,
  epsilon_squared = NULL,
  cohens_g = NULL,
  rank_biserial = NULL,
  rank_epsilon_squared = NULL,
  kendalls_w = NULL,
  . . .
)
## S3 method for class 'coeftest'
model_parameters(
 model,
 ci = 0.95,
 ci_method = "wald",
 keep = NULL,
 drop = NULL,
 verbose = TRUE,
  . . .
)
```

model	Object of class htest or pairwise.htest.
ci	Level of confidence intervals for effect size statistic. Currently only applies to objects from chisq.test() or oneway.test().
alternative	A character string specifying the alternative hypothesis; Controls the type of CI returned: "two.sided" (default, two-sided CI), "greater" or "less" (one-sided CI). Partial matching is allowed (e.g., "g", "l", "two"). See section <i>One-Sided CIs</i> in the effectsize_CIs vignette.
bootstrap	Should estimates be bootstrapped?
effectsize_type	
	The effect size of interest. Not that possibly not all effect sizes are applicable to the model object. See 'Details'. For Anova models, can also be a character vector with multiple effect size names.
verbose	Toggle warnings and messages.
cramers_v, phi,	<pre>cohens_g, standardized_d, hedges_g, omega_squared, eta_squared, epsilon_squared, rank_b Deprecated. Please use effectsize_type.</pre>
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().
ci_method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite",

"kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section *Confidence intervals and approximation of degrees of freedom* in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.

Character containing a regular expression pattern that describes the parameters keep that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the "Parameter" column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names. drop See keep.

Details

- For an object of class htest, data is extracted via insight::get_data(), and passed to the relevant function according to:
 - A t-test depending on type: "cohens_d" (default), "hedges_g", or one of "p_superiority", "u1", "u2", "u3", "overlap".
 - * For a **Paired t-test**: depending on type: "rm_rm", "rm_av", "rm_b", "rm_d", "rm_z".
 - A Chi-squared tests of independence or Fisher's Exact Test, depending on type: "cramers_v" (default), "tschuprows_t", "phi", "cohens_w", "pearsons_c", "cohens_h", "oddsratio", "riskratio", "arr", or "nnt".
 - A Chi-squared tests of goodness-of-fit, depending on type: "fei" (default) "cohens_w", "pearsons_c"
 - A One-way ANOVA test, depending on type: "eta" (default), "omega" or "epsilon" -squared, "f", or "f2".
 - A McNemar test returns Cohen's g.
 - A Wilcoxon test depending on type: returns "rank_biserial" correlation (default) or one of "p_superiority", "vda", "u2", "u3", "overlap".
 - A Kruskal-Wallis test depending on type: "epsilon" (default) or "eta".
 - A **Friedman test** returns *Kendall's W*. (Where applicable, ci and alternative are taken from the htest if not otherwise provided.)
- For an object of class BFBayesFactor, using bayestestR::describe_posterior(),
 - A t-test depending on type: "cohens_d" (default) or one of "p_superiority", "u1", "u2", "u3", "overlap".
 - A correlation test returns *r*.

- A contingency table test, depending on type: "cramers_v" (default), "phi", "tschuprows_t", "cohens_w", "pearsons_c", "cohens_h", "oddsratio", or "riskratio", "arr", or "nnt".
- A proportion test returns *p*.
- Objects of class anova, aov, aovlist or afex_aov, depending on type: "eta" (default), "omega" or "epsilon" -squared, "f", or "f2".
- Other objects are passed to parameters::standardize_parameters().

For statistical models it is recommended to directly use the listed functions, for the full range of options they provide.

Value

A data frame of indices related to the model's parameters.

Examples

```
model <- cor.test(mtcars$mpg, mtcars$cyl, method = "pearson")</pre>
model_parameters(model)
model <- t.test(iris$Sepal.Width, iris$Sepal.Length)</pre>
model_parameters(model, effectsize_type = "hedges_g")
model <- t.test(mtcars$mpg ~ mtcars$vs)</pre>
model_parameters(model, effectsize_type = "hedges_g")
model <- t.test(iris$Sepal.Width, mu = 1)</pre>
model_parameters(model, effectsize_type = "cohens_d")
data(airquality)
airquality$Month <- factor(airquality$Month, labels = month.abb[5:9])</pre>
model <- pairwise.t.test(airquality$0zone, airquality$Month)</pre>
model_parameters(model)
smokers <- c(83, 90, 129, 70)</pre>
patients <- c(86, 93, 136, 82)
model <- suppressWarnings(pairwise.prop.test(smokers, patients))</pre>
model_parameters(model)
model <- suppressWarnings(chisq.test(table(mtcars$am, mtcars$cyl)))</pre>
```

```
model_parameters(model, effectsize_type = "cramers_v")
```

Description

Parameters from Bayesian models.

```

  exponentiate = FALSE,
  standardize = NULL,
  group_level = FALSE,
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
  . . .
)
```

model	Bayesian model (including SEM from blavaan . May also be a data frame with
	posterior samples, however, as_draws must be set to TRUE (else, for data frames
	NULL is returned).

centrality The point-estimates (centrality indices) to compute. Character (vector) or list
	<pre>with one or more of these options: "median", "mean", "MAP" (see map_estimate()), "trimmed" (which is just mean(x, trim = threshold)), "mode" or "all".</pre>
dispersion	Logical, if TRUE, computes indices of dispersion related to the estimate(s) (SD and MAD for mean and median, respectively). Dispersion is not available for "MAP" or "mode" centrality indices.
ci	Credible Interval (CI) level. Default to 0.95 (95%). See bayestestR::ci() for further details.
ci_method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi- dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details. When ci_method=NULL, in most cases "wald" is used then.
test	The indices of effect existence to compute. Character (vector) or list with one or more of these options: "p_direction" (or "pd"), "rope", "p_map", "equivalence_test" (or "equitest"), "bayesfactor" (or "bf") or "all" to compute all tests. For each "test", the corresponding bayestestR function is called (e.g. rope() or p_direction()) and its results included in the summary output.
rope_range	<pre>ROPE's lower and higher bounds. Should be a list of two values (e.g., c(-0.1, 0.1)) or "default". If "default", the bounds are set to x +- 0.1*SD(response).</pre>
rope_ci	The Credible Interval (CI) probability, corresponding to the proportion of HDI, to use for the percentage in ROPE.
bf_prior	Distribution representing a prior for the computation of Bayes factors / SI. Used if the input is a posterior, otherwise (in the case of models) ignored.
diagnostic	Diagnostic metrics to compute. Character (vector) or list with one or more of these options: "ESS", "Rhat", "MCSE" or "all".
priors	Add the prior used for each parameter.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the <i>"Parameter"</i> column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.

verbose	Toggle messages and warnings.
	Currently not used.
as_draws	Logical, if TRUE and model is of class data.frame, the data frame is treated as posterior samples and handled similar to Bayesian models. All arguments in are passed to model_parameters.draws().
effects	Should results for fixed effects, random effects or both be returned? Only applies to mixed models. May be abbreviated.
component	Which type of parameters to return, such as parameters for the conditional model, the zero-inflation part of the model, the dispersion term, or other auxiliary parameters be returned? Applies to models with zero-inflation and/or dispersion formula, or if parameters such as sigma should be included. May be abbreviated. Note that the <i>conditional</i> component is also called <i>count</i> or <i>mean</i> component, depending on the model. There are three convenient shortcuts: component = "all" returns all possible parameters. If component = "location", location parameters such as conditional, zero_inflated, or smooth_terms, are returned (everything that are fixed or random effects - depending on the effects argument - but no auxiliary parameters). For component = "distributional" (or "auxiliary"), components like sigma, dispersion, or beta (and other auxiliary parameters) are returned.
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
standardize	 The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly: The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed effects will be standardized. Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
group_level	Logical, for multilevel models (i.e. models with random effects) and when effects = "all" or effects = "random", include the parameters for each group level from random effects. If group_level = FALSE (the default), only informa- tion on SD and COR are shown.

Value

A data frame of indices related to the model's parameters.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

• Applies to *non-Bayesian models*. For *linear models*, CIs computed using the Wald method (SE and a *t-distribution with residual df*); p-values computed using the Wald method with a *t-distribution with residual df*. For other models, CIs computed using the Wald method (SE and a *normal distribution*); p-values computed using the Wald method with a *normal distribution*.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with m-l-1 approximated df*); p-values computed using the Wald method with a *t-distribution with m-l-1 approximated df*. See ci_ml1().

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normaldistribution* (note: this might change in a future update!)

"uniroot"

 Applies to non-Bayesian models of class glmmTMB. CIs computed by profiling the likelihood curve for a parameter, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a normal-distribution (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

"hdi"

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

• Applies to *Bayesian models* with proper priors. CIs computed as *support intervals* comparing the posterior samples against the prior samples; p-values are based on the *probability of direction*. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

Note

When standardize = "refit", columns diagnostic, bf_prior and priors refer to the *original* model. If model is a data frame, arguments diagnostic, bf_prior and priors are ignored.

There is also a plot()-method implemented in the see-package.

if (require("rstanarm")) {
  model <- suppressWarnings(stan_glm(
    Sepal.Length ~ Petal.Length * Species,
    data = iris, iter = 500, refresh = 0
  ))
  model_parameters(model)
}</pre>
```

model_parameters.mipo Parameters from multiply imputed repeated analyses

Description

Format models of class mira, obtained from mice::width.mids(), or of class mipo.

Usage

```
## S3 method for class 'mipo'
model_parameters(
 model,
 ci = 0.95,
 exponentiate = FALSE,
 p_adjust = NULL,
 keep = NULL,
 drop = NULL,
 verbose = TRUE,
  . . .
)
## S3 method for class 'mira'
model_parameters(
 model,
 ci = 0.95,
 exponentiate = FALSE,
  p_adjust = NULL,
  keep = NULL,
 drop = NULL,
  verbose = TRUE,
  . . .
)
```

Arguments

model	An object of class mira or mipo.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate

= "nongaussian" will only exponentiate coefficients from non-Gaussian families.

p_adjust	Character vector, if not NULL, indicates the method to adjust p-values. See <pre>stats::p.adjust()</pre> for details. Further possible adjustment methods are "tukey",
	"scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data

	frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, ev- ery parameter name in the " <i>Parameter</i> " column that matches the regular ex- pression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular ex- pression pattern should match the parameter names as they are stored in the re- turned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
	sparameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.

... Arguments passed to or from other methods.

Details

model_parameters() for objects of class mira works similar to summary(mice::pool()), i.e. it generates the pooled summary of multiple imputed repeated regression analyses.

```
library(parameters)
if (require("mice", quietly = TRUE)) {
    data(nhanes2)
    imp <- mice(nhanes2)
    fit <- with(data = imp, exp = lm(bmi ~ age + hyp + chl))
    model_parameters(fit)
}
# model_parameters() also works for models that have no "tidy"-method in mice
if (require("mice", quietly = TRUE) && require("gee", quietly = TRUE)) {
    data(warpbreaks)
    set.seed(1234)
    warpbreaks$tension[sample(1:nrow(warpbreaks), size = 10)] <- NA
    imp <- mice(warpbreaks)
    fit <- with(data = imp, expr = gee(breaks ~ tension, id = wool))</pre>
```

```
# does not work:
# summary(pool(fit))
model_parameters(fit)
}
# and it works with pooled results
if (require("mice")) {
    data("nhanes2")
    imp <- mice(nhanes2)
    fit <- with(data = imp, exp = lm(bmi ~ age + hyp + chl))
    pooled <- pool(fit)
model_parameters(pooled)
}
```

model_parameters.PCA Parameters from PCA, FA, CFA, SEM

Description

Format structural models from the psych or FactoMineR packages.

Usage

```
## S3 method for class 'PCA'
model_parameters(
 model,
  sort = FALSE,
  threshold = NULL,
 labels = NULL,
  verbose = TRUE,
  . . .
)
## S3 method for class 'lavaan'
model_parameters(
 model,
 ci = 0.95,
  standardize = FALSE,
  component = c("regression", "correlation", "loading", "defined"),
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
  . . .
```

```
116
```

)

```
## S3 method for class 'principal'
model_parameters(
   model,
   sort = FALSE,
   threshold = NULL,
   labels = NULL,
   verbose = TRUE,
   ...
)
```

Arguments

model	Model object.
sort	Sort the loadings.
threshold	A value between 0 and 1 indicates which (absolute) values from the loadings should be removed. An integer higher than 1 indicates the n strongest loadings to retain. Can also be "max", in which case it will only display the maximum loading per variable (the most simple structure).
labels	A character vector containing labels to be added to the loadings data. Usually, the question related to the item.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
standardize	Return standardized parameters (standardized coefficients). Can be TRUE (or "all" or "std.all") for standardized estimates based on both the variances of observed and latent variables; "latent" (or "std.lv") for standardized estimates based on the variances of the latent variables only; or "no_exogenous" (or "std.nox") for standardized estimates based on both the variances of observed and latent variables, but not the variances of exogenous covariates. See lavaan::standardizedsolution for details.
component	What type of links to return. Can be "all" or some of c("regression", "correlation", "loading", "variance", "mean").
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, ev- ery parameter name in the " <i>Parameter</i> " column that matches the regular ex- pression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter

components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.

drop

See keep.

Details

For the structural models obtained with **psych**, the following indices are present:

- **Complexity** (*Hoffman's, 1978; Pettersson and Turkheimer, 2010*) represents the number of latent components needed to account for the observed variables. Whereas a perfect simple structure solution has a complexity of 1 in that each item would only load on one factor, a solution with evenly distributed items has a complexity greater than 1.
- Uniqueness represents the variance that is 'unique' to the variable and not shared with other variables. It is equal to 1 communality (variance that is shared with other variables). A uniqueness of 0.20 suggests that 20% or that variable's variance is not shared with other variables in the overall factor model. The greater 'uniqueness' the lower the relevance of the variable in the factor model.
- MSA represents the Kaiser-Meyer-Olkin Measure of Sampling Adequacy (*Kaiser and Rice*, 1974) for each item. It indicates whether there is enough data for each factor give reliable results for the PCA. The value should be > 0.6, and desirable values are > 0.8 (*Tabachnick and Fidell*, 2013).

Value

A data frame of indices or loadings.

Note

There is also a plot()-method for lavaan models implemented in the see-package.

model_parameters.rma Parameters from Meta-Analysis

Description

Extract and compute indices and measures to describe parameters of meta-analysis models.

Usage

```
## S3 method for class 'rma'
model_parameters(
   model,
   ci = 0.95,
   bootstrap = FALSE,
   iterations = 1000,
   standardize = NULL,
   exponentiate = FALSE,
   include_studies = TRUE,
   keep = NULL,
   drop = NULL,
   verbose = TRUE,
   ...
)
```

Arguments

model	Model object.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.
standardize	The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:
	 The "refit" method does <i>not</i> standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as Im.beta) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) <i>before</i> fitting the model. For mixed models, when using methods other than "refit", only the fixed
	 effects will be standardized. Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
include_studies	
	eters for overall-effects are shown.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the " <i>Parameter</i> " column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter

	components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().

Value

A data frame of indices related to the model's parameters.

```
library(parameters)
mydat <<- data.frame(</pre>
  effectsize = c(-0.393, 0.675, 0.282, -1.398),
  stderr = c(0.317, 0.317, 0.13, 0.36)
)
if (require("metafor", quietly = TRUE)) {
  model <- rma(yi = effectsize, sei = stderr, method = "REML", data = mydat)</pre>
  model_parameters(model)
}
# with subgroups
if (require("metafor", quietly = TRUE)) {
  data(dat.bcg)
  dat <- escalc(</pre>
    measure = "RR",
    ai = tpos,
    bi = tneg,
    ci = cpos,
    di = cneg,
    data = dat.bcg
  )
  dat$alloc <- ifelse(dat$alloc == "random", "random", "other")</pre>
  d <<- dat
  model <- rma(yi, vi, mods = ~alloc, data = d, digits = 3, slab = author)</pre>
  model_parameters(model)
}
if (require("metaBMA", quietly = TRUE)) {
  data(towels)
  m <- suppressWarnings(meta_random(logOR, SE, study, data = towels))</pre>
  model_parameters(m)
}
```

model_parameters.t1way

Parameters from robust statistical objects in WRS2

Description

Parameters from robust statistical objects in WRS2

Usage

```
## S3 method for class 't1way'
model_parameters(model, keep = NULL, verbose = TRUE, ...)
```

Arguments

model	Object from WRS2 package.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the <i>"Parameter"</i> column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods.

Value

A data frame of indices related to the model's parameters.

```
if (require("WRS2") && packageVersion("WRS2") >= "1.1.3") {
  model <- t1way(libido ~ dose, data = viagra)
  model_parameters(model)
}</pre>
```

```
model_parameters.zcpglm
```

Parameters from Zero-Inflated Models

Description

Parameters from zero-inflated models (from packages like pscl, cplm or countreg).

Usage

```
## S3 method for class 'zcpglm'
model_parameters(
 model,
  ci = 0.95,
 bootstrap = FALSE,
  iterations = 1000,
  component = c("all", "conditional", "zi", "zero_inflated"),
  standardize = NULL,
  exponentiate = FALSE,
  p_adjust = NULL,
  keep = NULL,
  drop = NULL,
  summary = getOption("parameters_summary", FALSE),
  verbose = TRUE,
  . . .
)
## S3 method for class 'mhurdle'
model_parameters(
 model,
  ci = 0.95,
 component = c("all", "conditional", "zi", "zero_inflated", "infrequent_purchase", "ip",
    "auxiliary"),
  exponentiate = FALSE,
 p_adjust = NULL,
  keep = NULL,
 drop = NULL,
  verbose = TRUE,
  . . .
)
```

Arguments

model	A model with zero-inflation component.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
bootstrap	Should estimates be based on bootstrapped model? If TRUE, then arguments of Bayesian regressions apply (see also bootstrap_parameters()).

component Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.

standardize The method used for standardizing the parameters. Can be NULL (default; no standardization), "refit" (for re-fitting the model on standardized data) or one of "basic", "posthoc", "smart", "pseudo". See 'Details' in standardize_parameters(). Importantly:

- The "refit" method does *not* standardize categorical predictors (i.e. factors), which may be a different behaviour compared to other R packages (such as **lm.beta**) or other software packages (like SPSS). to mimic such behaviours, either use standardize="basic" or standardize the data with datawizard::standardize(force=TRUE) *before* fitting the model.
- For mixed models, when using methods other than "refit", only the fixed effects will be standardized.
- Robust estimation (i.e., vcov set to a value other than NULL) of standardized parameters only works when standardize="refit".
- exponentiate Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
- p_adjust Character vector, if not NULL, indicates the method to adjust p-values. See stats::p.adjust() for details. Further possible adjustment methods are "tukey", "scheffe", "sidak" and "none" to explicitly disable adjustment for emmGrid objects (from emmeans).
- keep Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, every parameter name in the *"Parameter"* column that matches the regular expression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one|two|three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter

	components, like in model_parameters.lavaan(). Note that the regular expression pattern should match the parameter names as they are stored in the returned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
summary	Logical, if TRUE, prints summary information about the model (model formula, number of observations, residual standard deviation and more).
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().

Value

A data frame of indices related to the model's parameters.

See Also

insight::standardize_names() to rename columns into a consistent, standardized naming scheme.

Examples

```
library(parameters)
if (require("pscl")) {
   data("bioChemists")
   model <- zeroinfl(art ~ fem + mar + kid5 + ment | kid5 + phd, data = bioChemists)
   model_parameters(model)
}</pre>
```

n_clusters

Find number of clusters in your data

Description

Similarly to n_factors() for factor / principal component analysis, n_clusters() is the main function to find out the optimal numbers of clusters present in the data based on the maximum consensus of a large number of methods.

Essentially, there exist many methods to determine the optimal number of clusters, each with pros and cons, benefits and limitations. The main n_clusters function proposes to run all of them, and find out the number of clusters that is suggested by the majority of methods (in case of ties, it will select the most parsimonious solution with fewer clusters).

Note that we also implement some specific, commonly used methods, like the Elbow or the Gap method, with their own visualization functionalities. See the examples below for more details.

n_clusters

Usage

```
n_clusters(
  х,
  standardize = TRUE,
  include_factors = FALSE,
  package = c("easystats", "NbClust", "mclust"),
  fast = TRUE,
  nbclust_method = "kmeans",
  n_max = 10,
  . . .
)
n_clusters_elbow(
  х,
  standardize = TRUE,
  include_factors = FALSE,
  clustering_function = stats::kmeans,
  n_max = 10,

  n_max = 10,
  . . .
)
n_clusters_dbscan(
  х,
  standardize = TRUE,
  include_factors = FALSE,
  method = c("kNN", "SS"),
  min_size = 0.1,
  eps_n = 50,
  eps_range = c(0.1, 3),
```

```
...
)
n_clusters_hclust(
    x,
    standardize = TRUE,
    include_factors = FALSE,
    distance_method = "correlation",
    hclust_method = "average",
    ci = 0.95,
    iterations = 100,
    ...
)
```

Arguments

х	A data frame.
standardize	Standardize the dataframe before clustering (default).
include_factors	
	Logical, if TRUE, factors are converted to numerical values in order to be in- cluded in the data for determining the number of clusters. By default, factors are removed, because most methods that determine the number of clusters need numeric input only.
package	Package from which methods are to be called to determine the number of clus- ters. Can be "all" or a vector containing "easystats", "NbClust", "mclust", and "M3C".
fast	If FALSE, will compute 4 more indices (sets index = "allong" in NbClust). This has been deactivated by default as it is computationally heavy.
nbclust_method	The clustering method (passed to NbClust::NbClust() as method).
n_max	Maximal number of clusters to test.
	Arguments passed to or from other methods. For instance, when bootstrap = TRUE, arguments like type or parallel are passed down to bootstrap_model().
clustering_func	tion, gap_method
	Other arguments passed to other functions. clustering_function is used by fviz_nbclust() and can be kmeans, cluster::pam, cluster::clara, cluster::fanny, and more. gap_method is used by cluster::maxSE to extract the optimal numbers of clusters (see its method argument).
<pre>method, min_size</pre>	e, eps_n, eps_range
	Arguments for DBSCAN algorithm.
distance_method	
	The distance method (passed to dist()). Used by algorithms relying on the distance matrix, such as hclust or dbscan.
hclust_method	The hierarchical clustering method (passed to hclust()).
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
iterations	The number of bootstrap replicates. This only apply in the case of bootstrapped frequentist models.

128

n_clusters

Note

There is also a plot()-method implemented in the see-package.

```
library(parameters)
```

```
if (require("mclust", quietly = TRUE) && require("NbClust", quietly = TRUE) &&
 require("cluster", quietly = TRUE) && require("see", quietly = TRUE)) {

 head(as.data.frame(x), n = 10) # Print 10 first rows
 plot(x)
}
```

n_factors

Number of components/factors to retain in PCA/FA

Description

This function runs many existing procedures for determining how many factors to retain/extract from factor analysis (FA) or dimension reduction (PCA). It returns the number of factors based on the maximum consensus between methods. In case of ties, it will keep the simplest model and select the solution with the fewer factors.

Usage

```
n_factors(
    x,
    type = "FA",
    rotation = "varimax",
    algorithm = "default",
    package = c("nFactors", "psych"),
    cor = NULL,
    safe = TRUE,
```

130

n_factors

```
n_max = NULL,
....
)
n_components(
    x,
    type = "PCA",
    rotation = "varimax",
    algorithm = "default",
    package = c("nFactors", "psych"),
    cor = NULL,
    safe = TRUE,
    ....
)
```

Arguments

x	A data frame.
type	Can be "FA" or "PCA", depending on what you want to do.
rotation	Only used for VSS (Very Simple Structure criterion, see psych::VSS()). The rotation to apply. Can be "none", "varimax", "quartimax", "bentlerT", "equamax", "varimin", "geominT" and "bifactor" for orthogonal rotations, and "promax", "oblimin", "simplimax", "bentlerQ", "geominQ", "biquartimin" and "cluster" for oblique transformations.
algorithm	Factoring method used by VSS. Can be "pa" for Principal Axis Factor Analysis, "minres" for minimum residual (OLS) factoring, "mle" for Maximum Likeli- hood FA and "pc" for Principal Components. "default" will select "minres" if type = "FA" and "pc" if type = "PCA".
package	Package from which respective methods are used. Can be "all" or a vector containing "nFactors", "psych", "PCDimension", "fit" or "EGAnet". Note that "fit" (which actually also relies on the psych package) and "EGAnet" can be very slow for bigger datasets. Thus, the default is c("nFactors", "psych"). You must have the respective packages installed for the methods to be used.
cor	An optional correlation matrix that can be used (note that the data must still be passed as the first argument). If NULL, will compute it by running cor() on the passed data.
safe	If TRUE, the function will run all the procedures in try blocks, and will only return those that work and silently skip the ones that may fail.
n_max	If set to a value (e.g., 10), will drop from the results all methods that suggest a higher number of components. The interpretation becomes 'from all the methods that suggested a number lower than n_max, the results are'.
	Arguments passed to or from other methods.

Details

<code>n_components()</code> is actually an alias for <code>n_factors()</code>, with different defaults for the function arguments.

Value

A data frame.

Note

There is also a plot()-method implemented in the see-package. n_components() is a convenient short-cut for n_factors(type = "PCA").

n_factors(mtcars, type = "PCA")
result <- n_factors(mtcars[1:5], type = "FA")</pre>
```

132

```
as.data.frame(result)
summary(result)
# Setting package = 'all' will increase the number of methods (but is slow)
n_factors(mtcars, type = "PCA", package = "all")
n_factors(mtcars, type = "FA", algorithm = "mle", package = "all")
```

parameters_type Type of model parameters

Description

In a regression model, the parameters do not all have the meaning. For instance, the intercept has to be interpreted as theoretical outcome value under some conditions (when predictors are set to 0), whereas other coefficients are to be interpreted as amounts of change. Others, such as interactions, represent changes in another of the parameter. The parameters_type function attempts to retrieve information and meaning of parameters. It outputs a dataframe of information for each parameters, such as the Type (whether the parameter corresponds to a factor or a numeric predictor, or whether it is a (regular) interaction or a nested one), the Link (whether the parameter can be interpreted as a mean value, the slope of an association or a difference between two levels) and, in the case of interactions, which other parameters is impacted by which parameter.

Usage

parameters_type(model, ...)

Arguments

model	A statistical model.
	Arguments passed to or from other methods

Value

A data frame.

Examples

library(parameters)

```
model <- lm(Sepal.Length ~ Petal.Length + Species, data = iris)
parameters_type(model)
model <- lm(Sepal.Length ~ Species + poly(Sepal.Width, 2), data = iris)
parameters_type(model)
model <- lm(Sepal.Length ~ Species + poly(Sepal.Width, 2, raw = TRUE), data = iris)
parameters_type(model)</pre>
```

```
# Interactions
model <- lm(Sepal.Length ~ Sepal.Width * Species, data = iris)</pre>
parameters_type(model)
model <- lm(Sepal.Length ~ Sepal.Width * Species * Petal.Length, data = iris)</pre>
parameters_type(model)
model <- lm(Sepal.Length ~ Species * Sepal.Width, data = iris)</pre>
parameters_type(model)
model <- lm(Sepal.Length ~ Species / Sepal.Width, data = iris)</pre>
parameters_type(model)
# Complex interactions
data <- iris
data$fac2 <- ifelse(data$Sepal.Width > mean(data$Sepal.Width), "A", "B")
model <- lm(Sepal.Length ~ Species / fac2 / Petal.Length, data = data)</pre>
parameters_type(model)
model <- lm(Sepal.Length ~ Species / fac2 * Petal.Length, data = data)</pre>
parameters_type(model)
```

pool_parameters Pool Model Parameters

Description

This function "pools" (i.e. combines) model parameters in a similar fashion as mice::pool(). However, this function pools parameters from parameters_model objects, as returned by model_parameters().

Usage

```
pool_parameters(
    x,
    exponentiate = FALSE,
    effects = "fixed",
    component = "conditional",
    verbose = TRUE,
    ...
)
```

Arguments

х

A list of parameters_model objects, as returned by model_parameters(), or a list of model-objects that is supported by model_parameters().

exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
effects	Should parameters for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. If the calculation of random effects parameters takes too long, you may use effects = "fixed".
component	Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.
verbose	Toggle warnings and messages.
	Arguments passed down to model_parameters(), if x is a list of model-objects. Can be used, for instance, to specify arguments like ci or ci_method etc.

Details

Averaging of parameters follows Rubin's rules (*Rubin, 1987, p. 76*). The pooled degrees of freedom is based on the Barnard-Rubin adjustment for small samples (*Barnard and Rubin, 1999*).

Value

A data frame of indices related to the model's parameters.

Note

Models with multiple components, (for instance, models with zero-inflation, where predictors appear in the count and zero-inflation part) may fail in case of identical names for coefficients in the different model components, since the coefficient table is grouped by coefficient names for pooling. In such cases, coefficients of count and zero-inflation model parts would be combined. Therefore, the component argument defaults to "conditional" to avoid this.

Some model objects do not return standard errors (e.g. objects of class htest). For these models, no pooled confidence intervals nor p-values are returned.

Examples

```
# example for multiple imputed datasets
data("nhanes2", package = "mice")
imp <- mice::mice(nhanes2, printFlag = FALSE)</pre>
models <- lapply(1:5, function(i) {</pre>
 lm(bmi ~ age + hyp + chl, data = mice::complete(imp, action = i))
})
pool_parameters(models)
# should be identical to:
m <- with(data = imp, exp = lm(bmi ~ age + hyp + chl))</pre>
summary(mice::pool(m))
# For glm, mice used residual df, while `pool_parameters()` uses `Inf`
nhanes2$hyp <- datawizard::slide(as.numeric(nhanes2$hyp))</pre>
imp <- mice::mice(nhanes2, printFlag = FALSE)</pre>
models <- lapply(1:5, function(i) {</pre>
 glm(hyp ~ age + chl, family = binomial, data = mice::complete(imp, action = i))
})
m <- with(data = imp, exp = glm(hyp ~ age + chl, family = binomial))</pre>
# residual df
summary(mice::pool(m))$df
# df = Inf
pool_parameters(models)$df_error
# use residual df instead
pool_parameters(models, ci_method = "residual")$df_error
```

Description

Predict method for parameters_clusters objects

Usage

```
## S3 method for class 'parameters_clusters'
predict(object, newdata = NULL, names = NULL, ...)
```

Arguments

object	a model object for which prediction is desired.
newdata	data.frame
names	character vector or list
	additional arguments affecting the predictions produced.

136

print.parameters_model

Print model parameters

Description

A print()-method for objects from model_parameters().

Usage

```
## S3 method for class 'parameters_model'
print(
  х,
  pretty_names = TRUE,
  split_components = TRUE,
  select = NULL,
  caption = NULL,
  footer = NULL,
  digits = 2,
  ci_digits = digits,
  p_digits = 3,
  footer_digits = 3,
  show_sigma = FALSE,
  show_formula = FALSE,
  zap_small = FALSE,
  groups = NULL,
  column_width = NULL,
  ci_brackets = c("[", "]"),
  include_reference = FALSE,
  . . .
)
## S3 method for class 'parameters_model'
```

summary(object, ...)

Arguments

x, object	An object returned by model_parameters().
pretty_names	Can be TRUE, which will return "pretty" (i.e. more human readable) parameter names. Or "labels", in which case value and variable labels will be used as parameters names. The latter only works for "labelled" data, i.e. if the data used to fit the model had "label" and "labels" attributes. See also section <i>Global Options to Customize Messages when Printing</i> .
<pre>split_component</pre>	S

Logical, if TRUE (default), For models with multiple components (zero-inflation, smooth terms, ...), each component is printed in a separate table. If FALSE, model

parameters are printed in a single table and a Component column is added to the output.

Determines which columns and and which layout columns are printed. There are three options for this argument:

1. Selecting columns by name or index

select can be a character vector (or numeric index) of column names that should be printed. There are two pre-defined options for selecting columns: select = "minimal" prints coefficients, confidence intervals and p-values, while select = "short" prints coefficients, standard errors and p-values.

- 2. A string expression with layout pattern select is a string with "tokens" enclosed in braces. These tokens will be replaced by their associated columns, where the selected columns will be collapsed into one column. However, it is possible to create multiple columns as well. Following tokens are replaced by the related coefficients or statistics: {estimate}, {se}, {ci} (or {ci_low} and {ci_high}), {p} and {stars}. The token {ci} will be replaced by {ci_low}, {ci_high}. Furthermore, a | separates values into new cells/columns. If format =
 - "html", a
 inserts a line break inside a cell. See 'Examples'.
- 3. A string indicating a pre-defined layout

select can be one of the following string values, to create one of the following pre-defined column layouts:

- "ci": Estimates and confidence intervals, no asterisks for p-values. This is equivalent to select = "{estimate} ({ci})".
- "se": Estimates and standard errors, no asterisks for p-values. This is equivalent to select = "{estimate} ({se})".
- "ci_p": Estimates, confidence intervals and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({ci})".
- "se_p": Estimates, standard errors and asterisks for p-values. This is equivalent to select = "{estimate}{stars} ({se})"..
- "ci_p2": Estimates, confidence intervals and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({ci})|{p}".
- "se_p2": Estimate, standard errors and numeric p-values, in two columns. This is equivalent to select = "{estimate} ({se})|{p}".

For model_parameters(), glue-like syntax is still experimental in the case of more complex models (like mixed models) and may not return expected results.

caption	Table caption as string. If NULL, depending on the model, either a default caption
	or no table caption is printed. Use caption = "" to suppress the table caption.
footer	Can either be FALSE or an empty string (i.e. "") to suppress the footer, NULL to

print the default footer, or a string. The latter will combine the string value with the default footer.

digits, ci_digits, p_digits

Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

select

footer digits	Number of decimal places for values in the footer summary	
Tooler_uigits	Number of deema places for values in the footer summary.	
show_sigma	Logical, if TRUE, adds information about the residual standard deviation.	
show_formula	Logical, if TRUE, adds the model formula to the output.	
zap_small	Logical, if TRUE, small values are rounded after digits decimal places. If FALSE, values with more decimal places than digits are printed in scientific notation.	
groups	Named list, can be used to group parameters in the printed output. List elements may either be character vectors that match the name of those parameters that be- long to one group, or list elements can be row numbers of those parameter rows that should belong to one group. The names of the list elements will be used as group names, which will be inserted as "header row". A possible use case might be to emphasize focal predictors and control variables, see 'Examples'. Parameters will be re-ordered according to the order used in groups, while all non-matching parameters will be added to the end.	
column_width	Width of table columns. Can be either NULL, a named numeric vector, or "fixed" If NULL, the width for each table column is adjusted to the minimum required width. If a named numeric vector, value names are matched against column names, and for each match, the specified width is used. If "fixed", and table is split into multiple components, columns across all table components are adjusted to have the same width.	
ci_brackets	Logical, if TRUE (default), CI-values are encompassed in square brackets (else in parentheses).	
include_reference		
	Logical, if TRUE, the reference level of factors will be added to the parameters table. This is only relevant for models with categorical predictors. The coefficient for the reference level is always 0 (except when exponentiate = TRUE, then the coefficient will be 1), so this is just for completeness.	
	Arguments passed to or from other methods.	

Details

summary() is a convenient shortcut for print(object, select = "minimal", show_sigma = TRUE, show_formula = TRUE).

Value

Invisibly returns the original input object.

Global Options to Customize Messages and Tables when Printing

The verbose argument can be used to display or silence messages and warnings for the different functions in the **parameters** package. However, some messages providing additional information can be displayed or suppressed using options():

• parameters_summary: options(parameters_summary = TRUE) will override the summary argument in model_parameters() and always show the model summary for non-mixed models.

- parameters_mixed_summary: options(parameters_mixed_summary = TRUE) will override the summary argument in model_parameters() for mixed models, and will then always show the model summary.
- parameters_cimethod: options(parameters_cimethod = TRUE) will show the additional information about the approximation method used to calculate confidence intervals and p-values. Set to FALSE to hide this message when printing model_parameters() objects.
- parameters_exponentiate: options(parameters_exponentiate = TRUE) will show the
 additional information on how to interpret coefficients of models with log-transformed response variables or with log-/logit-links when the exponentiate argument in model_parameters()
 is not TRUE. Set this option to FALSE to hide this message when printing model_parameters()
 objects.

There are further options that can be used to modify the default behaviour for printed outputs:

- parameters_labels: options(parameters_labels = TRUE) will use variable and value labels for pretty names, if data is labelled. If no labels available, default pretty names are used.
- parameters_interaction: options(parameters_interaction = <character>) will replace the interaction mark (by default, *) with the related character.
- parameters_select: options(parameters_select = <value>) will set the default for the select argument. See argument's documentation for available options.
- easystats_html_engine: options(easystats_html_engine = "gt") will set the default HTML engine for tables to gt, i.e. the *gt* package is used to create HTML tables. If set to tt, the *tinytable* package is used.

Interpretation of Interaction Terms

Note that the *interpretation* of interaction terms depends on many characteristics of the model. The number of parameters, and overall performance of the model, can differ *or not* between a * b a : b, and a / b, suggesting that sometimes interaction terms give different parameterizations of the same model, but other times it gives completely different models (depending on a or b being factors of covariates, included as main effects or not, etc.). Their interpretation depends of the full context of the model, which should not be inferred from the parameters table alone - rather, we recommend to use packages that calculate estimated marginal means or marginal effects, such as **modelbased**, **emmeans**, **ggeffects**, or **marginaleffects**. To raise awareness for this issue, you may use print(..., show_formula=TRUE) to add the model-specification to the output of the print() method for model_parameters().

Labeling the Degrees of Freedom

Throughout the **parameters** package, we decided to label the residual degrees of freedom df_error . The reason for this is that these degrees of freedom not always refer to the residuals. For certain models, they refer to the estimate error - in a linear model these are the same, but in - for instance - any mixed effects model, this isn't strictly true. Hence, we think that df_error is the most generic label for these degrees of freedom.

print_html(result)
```

p calibrate	Calculate calibrated 1	>-value
p_caribrate)-vui

Description

Compute calibrated p-values that can be interpreted probabilistically, i.e. as posterior probability of H0 (given that H0 and H1 have equal prior probabilities).

Usage

```
p_calibrate(x, ...)
## Default S3 method:
p_calibrate(x, type = "frequentist", verbose = TRUE, ...)
```

Arguments

х	A numeric vector of p-values, or a regression model object.
	Currently not used.
type	Type of calibration. Can be "frequentist" or "bayesian". See 'Details'
verbose	Toggle warnings.

```
142
```

p_function

Details

The Bayesian calibration, i.e. when type = "bayesian", can be interpreted as the lower bound of the Bayes factor for H0 to H1, based on the data. The full Bayes factor would then require multiplying by the prior odds of H0 to H1. The frequentist calibration also has a Bayesian interpretation; it is the posterior probability of H0, assuming that H0 and H1 have equal prior probabilities of 0.5 each (*Sellke et al. 2001*).

The calibration only works for p-values lower than or equal to 1/e.

Value

A data frame with p-values and calibrated p-values.

References

Thomas Sellke, M. J Bayarri and James O Berger (2001) Calibration of p Values for Testing Precise Null Hypotheses, The American Statistician, 55:1, 62-71, doi:10.1198/000313001300339950

Examples

```
model <- lm(mpg ~ wt + as.factor(gear) + am, data = mtcars)
p_calibrate(model, verbose = FALSE)</pre>
```

p_function

p-value or consonance function

Description

Compute p-values and compatibility (confidence) intervals for statistical models, at different levels. This function is also called consonance function. It allows to see which estimates are compatible with the model at various compatibility levels. Use plot() to generate plots of the *p* resp. *consonance* function and compatibility intervals at different levels.

Usage

```
p_function(
  model,
  ci_levels = c(0.25, 0.5, 0.75, emph = 0.95),
  exponentiate = FALSE,
  effects = "fixed",
  component = "all",
  keep = NULL,
  drop = NULL,
  verbose = TRUE,
  ...
)
```

consonance_function(

```
model,
 ci_levels = c(0.25, 0.5, 0.75, emph = 0.95),
  exponentiate = FALSE,
 effects = "fixed",
  component = "all",
 keep = NULL,
 drop = NULL,
 verbose = TRUE,
  . . .
)
confidence_curve(
 model,
  ci_levels = c(0.25, 0.5, 0.75, emph = 0.95),
  exponentiate = FALSE,
 effects = "fixed",
  component = "all",
 keep = NULL,
 drop = NULL,
 verbose = TRUE,
  . . .
)
```

Arguments

model	Statistical Model.
ci_levels	Vector of scalars, indicating the different levels at which compatibility intervals should be printed or plotted. In plots, these levels are highlighted by vertical lines. It is possible to increase thickness for one or more of these lines by providing a names vector, where the to be highlighted values should be named "emph", e.g ci_levels = $c(0.25, 0.5, emph = 0.95)$.
exponentiate	Logical, indicating whether or not to exponentiate the coefficients (and related confidence intervals). This is typical for logistic regression, or more generally speaking, for models with log or logit links. It is also recommended to use exponentiate = TRUE for models with log-transformed response values. Note: Delta-method standard errors are also computed (by multiplying the standard errors by the transformed coefficients). This is to mimic behaviour of other software packages, such as Stata, but these standard errors poorly estimate uncertainty for the transformed coefficient. The transformed confidence interval more clearly captures this uncertainty. For compare_parameters(), exponentiate = "nongaussian" will only exponentiate coefficients from non-Gaussian families.
effects	Should parameters for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. If the calculation of random effects parameters takes too long, you may use effects = "fixed".
component	Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models

144
	with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.
keep	Character containing a regular expression pattern that describes the parameters that should be included (for keep) or excluded (for drop) in the returned data frame. keep may also be a named list of regular expressions. All non-matching parameters will be removed from the output. If keep is a character vector, ev- ery parameter name in the " <i>Parameter</i> " column that matches the regular ex- pression in keep will be selected from the returned data frame (and vice versa, all parameter names matching drop will be excluded). Furthermore, if keep has more than one element, these will be merged with an OR operator into a regular expression pattern like this: "(one two three)". If keep is a named list of regular expression patterns, the names of the list-element should equal the column name where selection should be applied. This is useful for model objects where model_parameters() returns multiple columns with parameter components, like in model_parameters.lavaan(). Note that the regular ex- pression pattern should match the parameter names as they are stored in the re- turned data frame, which can be different from how they are printed. Inspect the \$Parameter column of the parameters table to get the exact parameter names.
drop	See keep.
verbose	Toggle warnings and messages.
	Arguments passed to or from other methods. Non-documented arguments are digits, p_digits, ci_digits and footer_digits to set the number of digits for the output. If s_value = TRUE, the p-value will be replaced by the S-value in the output (cf. <i>Rafi and Greenland 2020</i>). pd adds an additional column with the <i>probability of direction</i> (see bayestestR::p_direction() for details). groups can be used to group coefficients. It will be passed to the print-method, or can directly be used in print(), see documentation in print.parameters_model(). Furthermore, see 'Examples' in model_parameters.default(). For developers, whose interest mainly is to get a "tidy" data frame of model summaries, it is recommended to set pretty_names = FALSE to speed up computation of the summary table.

Details

Compatibility intervals and continuous *p*-values for different estimate values:

p_function() only returns the compatibility interval estimates, not the related *p*-values. The reason for this is because the *p*-value for a given estimate value is just $1 - CI_level$. The values indicating the lower and upper limits of the intervals are the related estimates associated with the *p*-value. E.g., if a parameter x has a 75% compatibility interval of (0.81, 1.05), then the *p*-value for the estimate value of 0.81 would be 1 - 0.75, which is 0.25. This relationship is more intuitive and better to understand when looking at the plots (using plot()).

Conditional versus unconditional interpretation of *p*-values and intervals:

p_function(), and in particular its plot() method, aims at re-interpreting *p*-values and confidence intervals (better named: *compatibility* intervals) in *unconditional* terms. Instead of referring to the long-term property and repeated trials when interpreting interval estimates (so-called

"aleatory probability", *Schweder 2018*), and assuming that all underlying assumptions are correct and met, p_function() interprets *p*-values in a Fisherian way as "*continuous* measure of evidence against the very test hypothesis *and* entire model (all assumptions) used to compute it" (*P-Values Are Tough and S-Values Can Help*, lesslikely.com/statistics/s-values; see also *Amrhein and Greenland 2022*).

This interpretation as a continuous measure of evidence against the test hypothesis and the entire model used to compute it can be seen in the figure below (taken from *P-Values Are Tough and S-Values Can Help*, lesslikely.com/statistics/s-values). The "conditional" interpretation of *p*-values and interval estimates (A) implicitly assumes certain assumptions to be true, thus the interpretation is "conditioned" on these assumptions (i.e. assumptions are taken as given). The unconditional interpretation (B), however, questions all these assumptions.

"Emphasizing unconditional interpretations helps avoid overconfident and misleading inferences in light of uncertainties about the assumptions used to arrive at the statistical results." (*Greenland et al. 2022*).

Note: The term "conditional" as used by Rafi and Greenland probably has a slightly different meaning than normally. "Conditional" in this notion means that all model assumptions are taken as given - it should not be confused with terms like "conditional probability". See also *Greenland et al.* 2022 for a detailed elaboration on this issue.

In other words, the term compatibility interval emphasizes "the dependence of the *p*-value on the assumptions as well as on the data, recognizing that p<0.05 can arise from assumption violations even if the effect under study is null" (*Gelman/Greenland 2019*).

Probabilistic interpretation of compatibility intervals:

Schweder (2018) resp. Schweder and Hjort (2016) (and others) argue that confidence curves (as produced by p_function()) have a valid probabilistic interpretation. They distinguish between *aleatory probability*, which describes the aleatory stochastic element of a distribution *ex ante*, i.e. before the data are obtained. This is the classical interpretation of confidence intervals following the Neyman-Pearson school of statistics. However, there is also an *ex post* probability, called *epistemic* probability, for confidence curves. The shift in terminology from *confidence* intervals to *compatibility* intervals may help emphasizing this interpretation.

In this sense, the probabilistic interpretation of *p*-values and compatibility intervals is "conditional" - on the data *and* model assumptions (which is in line with the "unconditional" interpretation in the sense of Rafi and Greenland).

Ascribing a probabilistic interpretation to one realized confidence interval is possible without repeated sampling of the specific experiment. Important is the assumption that a *sampling distribution* is a good description of the variability of the parameter (*Vos and Holbert 2022*). At the core, the interpretation of a confidence interval is "I assume that this sampling distribution is a good description of the uncertainty of the parameter. If that's a good assumption, then the values in this interval are the most plausible or compatible with the data". The source of confidence in probability statements is the assumption that the selected sampling distribution is appropriate.

"The realized confidence distribution is clearly an epistemic probability distribution" (*Schweder* 2018). In Bayesian words, compatibility intervals (or confidence distributons, or consonance curves) are "posteriors without priors" (*Schweder, Hjort, 2003*). In this regard, interpretation of *p*-values might be guided using bayestestR::p_to_pd().

Compatibility intervals - is their interpretation conditional or not?:

The fact that the term "conditional" is used in different meanings, is confusing and unfortunate. Thus, we would summarize the probabilistic interpretation of compatibility intervals as follows:

p_function

The intervals are built from the data *and* our modeling assumptions. The accuracy of the intervals depends on our model assumptions. If a value is outside the interval, that might be because (1) that parameter value isn't supported by the data, or (2) the modeling assumptions are a poor fit for the situation. When we make bad assumptions, the compatibility interval might be too wide or (more commonly and seriously) too narrow, making us think we know more about the parameter than is warranted.

When we say "there is a 95% chance the true value is in the interval", that is a statement of *epistemic probability* (i.e. description of uncertainty related to our knowledge or belief). When we talk about repeated samples or sampling distributions, that is referring to *aleatoric* (physical properties) probability. Frequentist inference is built on defining estimators with known *aleatoric* probability properties, from which we can draw *epistemic* probabilistic statements of uncertainty (*Schweder and Hjort 2016*).

Value

A data frame with p-values and compatibility intervals.

Note

Curently, p_function() computes intervals based on Wald t- or z-statistic. For certain models (like mixed models), profiled intervals may be more accurate, however, this is currently not supported.

Examples

```
model <- lm(Sepal.Length ~ Species, data = iris)
p_function(model)
model <- lm(mpg ~ wt + as.factor(gear) + am, data = mtcars)
result <- p_function(model)
# single panels
plot(result, n_columns = 2)
# integrated plot, the default
plot(result)</pre>
```

p_value

p-values

Description

This function attempts to return, or compute, p-values of a model's parameters. See the documentation for your object's class:

- Bayesian models (rstanarm, brms, MCMCglmm, ...)
- Zero-inflated models (hurdle, zeroinfl, zerocount, ...)
- Marginal effects models (mfx)

p_value(model, ...)

• Models with special components (DirichletRegModel, clm2, cgam, ...)

Usage

```
## Default S3 method:
p_value(
    model,
    dof = NULL,
    method = NULL,
    component = "all",
    vcov = NULL,
    vcov_args = NULL,
    verbose = TRUE,
    ...
)
## S3 method for class 'emmGrid'
p_value(model, ci = 0.95, adjust = "none", ...)
```

p_value

Arguments

model	A statistical model.
	Additional arguments
dof	Number of degrees of freedom to be used when calculating confidence intervals. If NULL (default), the degrees of freedom are retrieved by calling degrees_of_freedom() with approximation method defined in method. If not NULL, use this argument to override the default degrees of freedom used to compute confidence intervals.
method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi- dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details.
component	Model component for which parameters should be shown. See the documenta- tion for your object's class in model_parameters() or p_value() for further details.
vcov	Variance-covariance matrix used to compute uncertainty estimates (e.g., for ro- bust standard errors). This argument accepts a covariance matrix, a function which returns a covariance matrix, or a string which identifies the function to be used to compute the covariance matrix.
	• A covariance matrix
	• A function which returns a covariance matrix (e.g., stats::vcov())
	• A string which indicates the kind of uncertainty estimates to return.
	 Heteroskedasticity-consistent: "vcovHC", "HC", "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". See ?sandwich::vcovHC.
	 Cluster-robust: "vcovCR", "CR0", "CR1", "CR1p", "CR1S", "CR2", "CR3". See ?clubSandwich::vcovCR.
	 Bootstrap: "vcovBS", "xy", "residual", "wild", "mammen", "webb". See ?sandwich::vcovBS.
	 Other sandwich package functions: "vcovHAC", "vcovPC", "vcovCL", "vcovPL".
vcov_args	List of arguments to be passed to the function identified by the vcov argument. This function is typically supplied by the sandwich or clubSandwich packages. Please refer to their documentation (e.g., ?sandwich::vcovHAC) to see the list of available arguments.
verbose	Toggle warnings and messages.
ci	Confidence Interval (CI) level. Default to 0.95 (95%).
adjust	Character value naming the method used to adjust p-values or confidence inter- vals. See ?emmeans::summary.emmGrid for details.

Value

A data frame with at least two columns: the parameter names and the p-values. Depending on the model, may also include columns for model components etc.

Confidence intervals and approximation of degrees of freedom

There are different ways of approximating the degrees of freedom depending on different assumptions about the nature of the model and its sampling distribution. The ci_method argument modulates the method for computing degrees of freedom (df) that are used to calculate confidence intervals (CI) and the related p-values. Following options are allowed, depending on the model class:

Classical methods:

Classical inference is generally based on the **Wald method**. The Wald approach to inference computes a test statistic by dividing the parameter estimate by its standard error (Coefficient / SE), then comparing this statistic against a t- or normal distribution. This approach can be used to compute CIs and p-values.

"wald":

• Applies to *non-Bayesian models*. For *linear models*, CIs computed using the Wald method (SE and a *t-distribution with residual df*); p-values computed using the Wald method with a *t-distribution with residual df*. For other models, CIs computed using the Wald method (SE and a *normal distribution*); p-values computed using the Wald method with a *normal distribution*.

"normal"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a normal distribution.

"residual"

• Applies to *non-Bayesian models*. Compute Wald CIs and p-values, but always use a *t-distribution with residual df* when possible. If the residual df for a model cannot be determined, a normal distribution is used instead.

Methods for mixed models:

Compared to fixed effects (or single-level) models, determining appropriate df for Wald-based inference in mixed models is more difficult. See the R GLMM FAQ for a discussion.

Several approximate methods for computing df are available, but you should also consider instead using profile likelihood ("profile") or bootstrap ("boot") CIs and p-values instead.

"satterthwaite"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with Satterthwaite df*); p-values computed using the Wald method with a *t-distribution with Satterthwaite df*.

"kenward"

• Applies to *linear mixed models*. CIs computed using the Wald method (*Kenward-Roger SE* and a *t-distribution with Kenward-Roger df*); p-values computed using the Wald method with *Kenward-Roger SE and t-distribution with Kenward-Roger df*.

"ml1"

• Applies to *linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with m-l-1 approximated df*); p-values computed using the Wald method with a *t-distribution with m-l-1 approximated df*. See ci_ml1().

p_value

"betwithin"

• Applies to *linear mixed models* and *generalized linear mixed models*. CIs computed using the Wald method (SE and a *t-distribution with between-within df*); p-values computed using the Wald method with a *t-distribution with between-within df*. See ci_betwithin().

Likelihood-based methods:

Likelihood-based inference is based on comparing the likelihood for the maximum-likelihood estimate to the the likelihood for models with one or more parameter values changed (e.g., set to zero or a range of alternative values). Likelihood ratios for the maximum-likelihood and alternative models are compared to a χ -squared distribution to compute CIs and p-values.

"profile"

• Applies to *non-Bayesian models* of class glm, polr, merMod or glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using linear interpolation to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

"uniroot"

• Applies to *non-Bayesian models* of class glmmTMB. CIs computed by *profiling the likelihood curve for a parameter*, using root finding to find where likelihood ratio equals a critical value; p-values computed using the Wald method with a *normal-distribution* (note: this might change in a future update!)

Methods for bootstrapped or Bayesian models:

Bootstrap-based inference is based on **resampling** and refitting the model to the resampled datasets. The distribution of parameter estimates across resampled datasets is used to approximate the parameter's sampling distribution. Depending on the type of model, several different methods for bootstrapping and constructing CIs and p-values from the bootstrap distribution are available.

For Bayesian models, inference is based on drawing samples from the model posterior distribution.

"quantile" (or "eti")

• Applies to *all models* (*including Bayesian models*). For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *equal tailed intervals* using the quantiles of the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::eti().

"hdi"

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *highest density intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::hdi().

"bci" (or "bcai")

• Applies to *all models (including Bayesian models)*. For non-Bayesian models, only applies if bootstrap = TRUE. CIs computed as *bias corrected and accelerated intervals* for the bootstrap or posterior samples; p-values are based on the *probability of direction*. See bayestestR::bci().

"si"

• Applies to *Bayesian models* with proper priors. CIs computed as *support intervals* comparing the posterior samples against the prior samples; p-values are based on the *probability of direction*. See bayestestR::si().

"boot"

• Applies to *non-Bayesian models* of class merMod. CIs computed using *parametric bootstrapping* (simulating data from the fitted model); p-values computed using the Wald method with a *normal-distribution*) (note: this might change in a future update!).

For all iteration-based methods other than "boot" ("hdi", "quantile", "ci", "eti", "si", "bci", "bcai"), p-values are based on the probability of direction (bayestestR::p_direction()), which is converted into a p-value using bayestestR::pd_to_p().

Examples

```
data(iris)
model <- lm(Petal.Length ~ Sepal.Length + Species, data = iris)
p_value(model)</pre>
```

p_value.BFBayesFactor p-values for Bayesian Models

Description

This function attempts to return, or compute, p-values of Bayesian models.

Usage

```
## S3 method for class 'BFBayesFactor'
p_value(model, ...)
```

Arguments

model	A statistical model.
	Additional arguments

Details

For Bayesian models, the p-values corresponds to the *probability of direction* (bayestestR::p_direction()), which is converted to a p-value using bayestestR::convert_pd_to_p().

Value

The p-values.

p_value.DirichletRegModel

Examples

```
data(iris)
model <- lm(Petal.Length ~ Sepal.Length + Species, data = iris)
p_value(model)</pre>
```

p_value.DirichletRegModel

p-values for Models with Special Components

Description

This function attempts to return, or compute, p-values of models with special model components.

Usage

```
## S3 method for class 'DirichletRegModel'
p_value(model, component = c("all", "conditional", "precision"), ...)
## S3 method for class 'averaging'
p_value(model, component = c("conditional", "full"), ...)
## S3 method for class 'betareg'
p_value(
    model,
    component = c("all", "conditional", "precision"),
    verbose = TRUE,
    ...
)
## S3 method for class 'cgam'
p_value(model, component = c("all", "conditional", "smooth_terms"), ...)
## S3 method for class 'clm2'
p_value(model, component = c("all", "conditional", "scale"), ...)
```

Arguments

model	A statistical model.
component	Should all parameters, parameters for the conditional model, precision- or scale- component or smooth_terms be returned? component may be one of "conditional", "precision", "scale", "smooth_terms", "full" or "all" (default).
	Additional arguments
verbose	Toggle warnings and messages.

Value

The p-values.

p_value.poissonmfx p-values for Marginal Effects Models

Description

This function attempts to return, or compute, p-values of marginal effects models from package **mfx**.

Usage

```
## S3 method for class 'poissonmfx'
p_value(model, component = c("all", "conditional", "marginal"), ...)
## S3 method for class 'betaor'
p_value(model, component = c("all", "conditional", "precision"), ...)
## S3 method for class 'betamfx'
p_value(
    model,
    component = c("all", "conditional", "precision", "marginal"),
    ...
)
```

Arguments

model	A statistical model.
component	Should all parameters, parameters for the conditional model, precision-component or marginal effects be returned? component may be one of "conditional", "precision", "marginal" or "all" (default).
	Currently not used.

Value

A data frame with at least two columns: the parameter names and the p-values. Depending on the model, may also include columns for model components etc.

Examples

```
if (require("mfx", quietly = TRUE)) {
    set.seed(12345)
    n <- 1000
    x <- rnorm(n)
    y <- rnegbin(n, mu = exp(1 + 0.5 * x), theta = 0.5)
    d <- data.frame(y, x)
    model <- poissonmfx(y ~ x, data = d)
    p_value(model)</pre>
```

```
p_value(model, component = "marginal")
}
```

p_value.zcpglm p-values for Models with Zero-Inflation

Description

This function attempts to return, or compute, p-values of hurdle and zero-inflated models.

Usage

```
## S3 method for class 'zcpglm'
p_value(model, component = c("all", "conditional", "zi", "zero_inflated"), ...)
## S3 method for class 'zeroinfl'
p_value(
    model,
    component = c("all", "conditional", "zi", "zero_inflated"),
    method = NULL,
    verbose = TRUE,
    ...
)
```

Arguments

model	A statistical model.
component	Model component for which parameters should be shown. See the documenta- tion for your object's class in model_parameters() or p_value() for further details.
	Additional arguments
method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi-</i> <i>dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details.
verbose	Toggle warnings and messages.

Value

A data frame with at least two columns: the parameter names and the p-values. Depending on the model, may also include columns for model components etc.

Examples

```
if (require("pscl", quietly = TRUE)) {
    data("bioChemists")
    model <- zeroinfl(art ~ fem + mar + kid5 | kid5 + phd, data = bioChemists)
    p_value(model)
    p_value(model, component = "zi")
}</pre>
```

Sample data set

qol_cancer

Description

A sample data set with longitudinal data, used in the vignette describing the datawizard::demean() function. Health-related quality of life from cancer-patients was measured at three time points (presurgery, 6 and 12 months after surgery).

Format

A data frame with 564 rows and 7 variables:

ID Patient ID
QoL Quality of Life Score
time Timepoint of measurement
age Age in years
phq4 Patients' Health Questionnaire, 4-item version
hospital Hospital ID, where patient was treated
education Patients' educational level

random_parameters Summary information from random effects

Description

This function extracts the different variance components of a mixed model and returns the result as a data frame.

Usage

```
random_parameters(model, component = "conditional")
```

model	A mixed effects model (including stanreg models).
component	Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.

Details

The variance components are obtained from insight::get_variance() and are denoted as following:

Within-group (or residual) variance:

The residual variance, σ_{ϵ}^2 , is the sum of the distribution-specific variance and the variance due to additive dispersion. It indicates the *within-group variance*.

Between-group random intercept variance:

The random intercept variance, or *between-group* variance for the intercept (τ_{00}), is obtained from VarCorr(). It indicates how much groups or subjects differ from each other.

Between-group random slope variance:

The random slope variance, or *between-group* variance for the slopes (τ_{11}) is obtained from VarCorr(). This measure is only available for mixed models with random slopes. It indicates how much groups or subjects differ from each other according to their slopes.

Random slope-intercept correlation:

The random slope-intercept correlation (ρ_{01}) is obtained from VarCorr(). This measure is only available for mixed models with random intercepts and slopes.

Note: For the within-group and between-group variance, variance and standard deviations (which are simply the square root of the variance) are shown.

Value

A data frame with random effects statistics for the variance components, including number of levels per random effect group, as well as complete observations in the model.

Examples

```
if (require("lme4")) {
   data(sleepstudy)
   model <- lmer(Reaction ~ Days + (1 + Days | Subject), data = sleepstudy)
   random_parameters(model)
}</pre>
```

reduce_parameters

Description

This function performs a reduction in the parameter space (the number of variables). It starts by creating a new set of variables, based on the given method (the default method is "PCA", but other are available via the method argument, such as "cMDS", "DRR" or "ICA"). Then, it names this new dimensions using the original variables that correlates the most with it. For instance, a variable named $'V1_0.97/V4_{-}0.88'$ means that the V1 and the V4 variables correlate maximally (with respective coefficients of .97 and -.88) with this dimension. Although this function can be useful in exploratory data analysis, it's best to perform the dimension reduction step in a separate and dedicated stage, as this is a very important process in the data analysis workflow. reduce_data() is an alias for reduce_parameters.data.frame().

Usage

```
reduce_parameters(x, method = "PCA", n = "max", distance = "euclidean", ...)
```

```
reduce_data(x, method = "PCA", n = "max", distance = "euclidean", ...)
```

Arguments

х	A data frame or a statistical model.
method	The feature reduction method. Can be one of "PCA", "cMDS", "DRR", "ICA" (see the 'Details' section).
n	Number of components to extract. If n="all", then n is set as the number of variables minus 1 (ncol(x)-1). If n="auto" (default) or n=NULL, the number of components is selected through n_factors() resp. n_components(). Else, if n is a number, n components are extracted. If n exceeds number of variables in the data, it is automatically set to the maximum number (i.e. ncol(x)). In reduce_parameters(), can also be "max", in which case it will select all the components that are maximally pseudo-loaded (i.e., correlated) by at least one variable.
distance	The distance measure to be used. Only applies when method = "cMDS". This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
	Arguments passed to or from other methods.

Details

The different methods available are described below:

Supervised Methods:

• **PCA**: See principal_components().

- **cMDS / PCoA**: Classical Multidimensional Scaling (cMDS) takes a set of dissimilarities (i.e., a distance matrix) and returns a set of points such that the distances between the points are approximately equal to the dissimilarities.
- **DRR**: Dimensionality Reduction via Regression (DRR) is a very recent technique extending PCA (*Laparra et al., 2015*). Starting from a rotated PCA, it predicts redundant information from the remaining components using non-linear regression. Some of the most notable advantages of performing DRR are avoidance of multicollinearity between predictors and overfitting mitigation. DRR tends to perform well when the first principal component is enough to explain most of the variation in the predictors. Requires the **DRR** package to be installed.
- ICA: Performs an Independent Component Analysis using the FastICA algorithm. Contrary to PCA, which attempts to find uncorrelated sources (through least squares minimization), ICA attempts to find independent sources, i.e., the source space that maximizes the "non-gaussianity" of all sources. Contrary to PCA, ICA does not rank each source, which makes it a poor tool for dimensionality reduction. Requires the **fastICA** package to be installed.

See also package vignette.

Examples

```
data(iris)
model <- lm(Sepal.Width ~ Species * Sepal.Length + Petal.Width, data = iris)
model
reduce_parameters(model)
out <- reduce_data(iris, method = "PCA", n = "max")
head(out)</pre>
```

reshape_loadings Reshape loadings between wide/long formats

Description

Reshape loadings between wide/long formats.

Usage

```
reshape_loadings(x, ...)
```

S3 method for class 'parameters_efa'

```
reshape_loadings(x, threshold = NULL, ...)
## S3 method for class 'data.frame'
```

reshape_loadings(x, threshold = NULL, loadings_columns = NULL, ...)

Arguments

x	A data frame or a statistical model.
	Arguments passed to or from other methods.
threshold	A value between 0 and 1 indicates which (absolute) values from the loadings should be removed. An integer higher than 1 indicates the n strongest loadings to retain. Can also be "max", in which case it will only display the maximum loading per variable (the most simple structure).
loadings_columns	

Vector indicating the columns corresponding to loadings.

Examples

```
if (require("psych")) {
  pca <- model_parameters(psych::fa(attitude, nfactors = 3))
  loadings <- reshape_loadings(pca)
  loadings
  reshape_loadings(loadings)
}</pre>
```

select_parameters Automated selection of model parameters

Description

This function performs an automated selection of the 'best' parameters, updating and returning the "best" model.

```
select_parameters(model, ...)
## S3 method for class 'lm'
select_parameters(model, direction = "both", steps = 1000, k = 2, ...)
## S3 method for class 'merMod'
select_parameters(model, direction = "backward", steps = 1000, ...)
```

select_parameters

Arguments

model	A statistical model (of class lm, glm, or merMod).
	Arguments passed to or from other methods.
direction	the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward". Values can be abbreviated.
steps	the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
k	the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = log(n)$ is sometimes referred to as BIC or SBC.

Details

Classical lm and glm: For frequentist GLMs, select_parameters() performs an AIC-based stepwise selection.

Mixed models: For mixed-effects models of class merMod, stepwise selection is based on cAIC4::stepcAIC(). This step function only searches the "best" model based on the random-effects structure, i.e. select_parameters() adds or excludes random-effects until the cAIC can't be improved further.

Value

The model refitted with optimal number of parameters.

Examples

```
model <- lm(mpg ~ ., data = mtcars)
select_parameters(model)

model <- lm(mpg ~ cyl * disp * hp * wt, data = mtcars)
select_parameters(model)

# lme4 ------
if (require("lme4")) {
   model <- lmer(
      Sepal.Width ~ Sepal.Length * Petal.Width * Petal.Length + (1 | Species),
      data = iris
   )
   select_parameters(model)
}</pre>
```

simulate_model

Description

Simulate draws from a statistical model to return a data frame of estimates.

Usage

```
simulate_model(model, iterations = 1000, ...)
## S3 method for class 'glmmTMB'
simulate_model(
   model,
   iterations = 1000,
   component = c("all", "conditional", "zi", "zero_inflated", "dispersion"),
   verbose = FALSE,
   ...
)
```

Arguments

model	Statistical model (no Bayesian models).
iterations	The number of draws to simulate/bootstrap.
	Arguments passed to insight::get_varcov(), e.g. to allow simulated draws to be based on heteroscedasticity consistent variance covariance matrices.
component	Should all parameters, parameters for the conditional model, for the zero-inflation part of the model, or the dispersion model be returned? Applies to models with zero-inflation and/or dispersion component. component may be one of "conditional", "zi", "zero-inflated", "dispersion" or "all" (default). May be abbreviated.
verbose	Toggle warnings and messages.

Details

Technical Details:

simulate_model() is a computationally faster alternative to bootstrap_model(). Simulated draws for coefficients are based on a multivariate normal distribution (MASS::mvrnorm()) with mean mu = coef(model) and variance Sigma = vcov(model).

Models with Zero-Inflation Component:

For models from packages **glmmTMB**, **pscl**, **GLMMadaptive** and **countreg**, the component argument can be used to specify which parameters should be simulated. For all other models, parameters from the conditional component (fixed effects) are simulated. This may include smooth terms, but not random effects.

Value

A data frame.

See Also

```
simulate_parameters(), bootstrap_model(), bootstrap_parameters()
```

Examples

```
model <- lm(Sepal.Length ~ Species * Petal.Width + Petal.Length, data = iris)
head(simulate_model(model))</pre>
```

```
if (require("glmmTMB", quietly = TRUE)) {
  model <- glmmTMB(
    count ~ spp + mined + (1 | site),
    ziformula = ~mined,
    family = poisson(),
    data = Salamanders
  )
  head(simulate_model(model))
  head(simulate_model(model, component = "zero_inflated"))
}</pre>
```

simulate_parameters.glmmTMB

Simulate Model Parameters

Description

Compute simulated draws of parameters and their related indices such as Confidence Intervals (CI) and p-values. Simulating parameter draws can be seen as a (computationally faster) alternative to bootstrapping.

```
## S3 method for class 'glmmTMB'
simulate_parameters(
   model,
   iterations = 1000,
   centrality = "median",
   ci = 0.95,
   ci_method = "quantile",
   test = "p-value",
   ...
)
simulate_parameters(model, ...)
```

```
## Default S3 method:
simulate_parameters(
  model,
  iterations = 1000,
  centrality = "median",
  ci = 0.95,
  ci_method = "quantile",
  test = "p-value",
  ...
)
```

model	Statistical model (no Bayesian models).
iterations	The number of draws to simulate/bootstrap.
centrality	The point-estimates (centrality indices) to compute. Character (vector) or list with one or more of these options: "median", "mean", "MAP" (see map_estimate()), "trimmed" (which is just mean(x, trim = threshold)), "mode" or "all".
ci	Value or vector of probability of the CI (between 0 and 1) to be estimated. Default to 0.95 (95%).
ci_method	The type of index used for Credible Interval. Can be "ETI" (default, see eti()), "HDI" (see hdi()), "BCI" (see bci()), "SPI" (see spi()), or "SI" (see si()).
test	The indices of effect existence to compute. Character (vector) or list with one or more of these options: "p_direction" (or "pd"), "rope", "p_map", "equivalence_test" (or "equitest"), "bayesfactor" (or "bf") or "all" to compute all tests. For each "test", the corresponding bayestestR function is called (e.g. rope() or p_direction()) and its results included in the summary output.
	Arguments passed to insight::get_varcov(), e.g. to allow simulated draws to be based on heteroscedasticity consistent variance covariance matrices.

Details

Technical Details:

simulate_parameters() is a computationally faster alternative to bootstrap_parameters().
Simulated draws for coefficients are based on a multivariate normal distribution (MASS::mvrnorm())
with mean mu = coef(model) and variance Sigma = vcov(model).

Models with Zero-Inflation Component:

For models from packages **glmmTMB**, **pscl**, **GLMMadaptive** and **countreg**, the component argument can be used to specify which parameters should be simulated. For all other models, parameters from the conditional component (fixed effects) are simulated. This may include smooth terms, but not random effects.

Value

A data frame with simulated parameters.

sort_parameters

Note

There is also a plot()-method implemented in the see-package.

  )
  simulate_parameters(model, centrality = "mean")
  simulate_parameters(model, ci = c(.8, .95), component = "zero_inflated")
}</pre>
```

sort_parameters Sort parameters by coefficient values

Description

Sort parameters by coefficient values

```
sort_parameters(x, ...)
## Default S3 method:
sort_parameters(x, sort = "none", column = "Coefficient", ...)
```

х	A data frame or a parameters_model object.
	Arguments passed to or from other methods.
sort	If "none" (default) do not sort, "ascending" sort by increasing coefficient value, or "descending" sort by decreasing coefficient value.
column	The column containing model parameter estimates. This will be "Coefficient" (default) in <i>easystats</i> packages, "estimate" in <i>broom</i> package, etc.

Value

A sorted data frame or original object.

Examples

```
# creating object to sort (can also be a regular data frame)
mod <- model_parameters(stats::lm(wt ~ am * cyl, data = mtcars))
# original output
mod
# sorted outputs
sort_parameters(mod, sort = "ascending")
sort_parameters(mod, sort = "descending")</pre>
```

standardize_info Get Standardization Information

Description

This function extracts information, such as the deviations (SD or MAD) from parent variables, that are necessary for post-hoc standardization of parameters. This function gives a window on how standardized are obtained, i.e., by what they are divided. The "basic" method of standardization uses.

```
standardize_info(model, ...)
## Default S3 method:
standardize_info(
  model,
  robust = FALSE,
  two_sd = FALSE,
  include_pseudo = FALSE,
  verbose = TRUE,
  ...
)
```

model	A statistical model.
	Arguments passed to or from other methods.
robust	Logical, if TRUE, centering is done by subtracting the median from the variables and dividing it by the median absolute deviation (MAD). If FALSE, variables are standardized by subtracting the mean and dividing it by the standard deviation (SD).
two_sd	If TRUE, the variables are scaled by two times the deviation (SD or MAD depending on robust). This method can be useful to obtain model coefficients of continuous parameters comparable to coefficients related to binary predictors, when applied to the predictors (not the outcome) (Gelman, 2008).
include_pseudo	(For (G)LMMs) Should Pseudo-standardized information be included?
verbose	Toggle warnings and messages on or off.

Value

A data frame with information on each parameter (see parameters_type()), and various standardization coefficients for the post-hoc methods (see standardize_parameters()) for the predictor and the response.

See Also

Other standardize: standardize_parameters()

Examples

```
model <- lm(mpg ~ ., data = mtcars)
standardize_info(model)
standardize_info(model, robust = TRUE)
standardize_info(model, two_sd = TRUE)</pre>
```

standardize_parameters

Parameters standardization

Description

Compute standardized model parameters (coefficients).

```
standardize_parameters(
  model,
  method = "refit",
  ci = 0.95,
  robust = FALSE,
```

```
two_sd = FALSE,
include_response = TRUE,
verbose = TRUE,
...
)
standardize_posteriors(
model,
method = "refit",
robust = FALSE,
two_sd = FALSE,
include_response = TRUE,
verbose = TRUE,
...
)
```

model	A statistical model.	
method	The method used for standardizing the parameters. Can be "refit" (default), "posthoc", "smart", "basic", "pseudo" or "sdy". See Details'.	
ci	Confidence Interval (CI) level	
robust	Logical, if TRUE, centering is done by subtracting the median from the variables and dividing it by the median absolute deviation (MAD). If FALSE, variables are standardized by subtracting the mean and dividing it by the standard deviation (SD).	
two_sd	If TRUE, the variables are scaled by two times the deviation (SD or MAD depending on robust). This method can be useful to obtain model coefficients of continuous parameters comparable to coefficients related to binary predictors, when applied to the predictors (not the outcome) (Gelman, 2008).	
include_response		
	If TRUE (default), the response value will also be standardized. If FALSE, only the predictors will be standardized. For GLMs the response value will never be standardized (see <i>Generalized Linear Models</i> section).	
verbose	Toggle warnings and messages on or off.	
	For standardize_parameters(), arguments passed to model_parameters(), such as:	
	 ci_method, centrality for Mixed models and Bayesian models exponentiate, etc. 	

Details

Standardization Methods:

• **refit**: This method is based on a complete model re-fit with a standardized version of the data. Hence, this method is equal to standardizing the variables before fitting the model. It is

the "purest" and the most accurate (Neter et al., 1989), but it is also the most computationally costly and long (especially for heavy models such as Bayesian models). This method is particularly recommended for complex models that include interactions or transformations (e.g., polynomial or spline terms). The robust (default to FALSE) argument enables a robust standardization of data, i.e., based on the median and MAD instead of the mean and SD. **See** standardize() for more details.

- Note that standardize_parameters(method = "refit") may not return the same results as fitting a model on data that has been standardized with standardize(); standardize_parameters() used the data used by the model fitting function, which might not be same data if there are missing values. see the remove_na argument in standardize().
- **posthoc**: Post-hoc standardization of the parameters, aiming at emulating the results obtained by "refit" without refitting the model. The coefficients are divided by the standard deviation (or MAD if robust) of the outcome (which becomes their expression 'unit'). Then, the coefficients related to numeric variables are additionally multiplied by the standard deviation (or MAD if robust) of the related terms, so that they correspond to changes of 1 SD of the predictor (e.g., "A change in 1 SD of x is related to a change of 0.24 of the SD of y). This does not apply to binary variables or factors, so the coefficients are still related to changes in levels. This method is not accurate and tend to give aberrant results when interactions are specified.
- **basic**: This method is similar to method = "posthoc", but treats all variables as continuous: it also scales the coefficient by the standard deviation of model's matrix' parameter of factors levels (transformed to integers) or binary predictors. Although being inappropriate for these cases, this method is the one implemented by default in other software packages, such as lm.beta::lm.beta().
- **smart** (Standardization of Model's parameters with Adjustment, Reconnaissance and Transformation *experimental*): Similar to method = "posthoc" in that it does not involve model refitting. The difference is that the SD (or MAD if robust) of the response is computed on the relevant section of the data. For instance, if a factor with 3 levels A (the intercept), B and C is entered as a predictor, the effect corresponding to B vs. A will be scaled by the variance of the response at the intercept only. As a results, the coefficients for effects of factors are similar to a Glass' delta.
- **pseudo** (for 2-level (G)LMMs only): In this (post-hoc) method, the response and the predictor are standardized based on the level of prediction (levels are detected with performance::check_heterogeneity_bia Predictors are standardized based on their SD at level of prediction (see also datawizard::demean()); The outcome (in linear LMMs) is standardized based on a fitted random-intercept-model, where sqrt(random-intercept-variance) is used for level 2 predictors, and sqrt(residual-variance) is used for level 1 predictors (Hoffman 2015, page 342). A warning is given when a withingroup variable is found to have access between-group variance.
- **sdy** (*for logistic regression models only*): This y-standardization is useful when comparing coefficients of logistic regression models across models for the same sample. Unobserved heterogeneity varies across models with different independent variables, and thus, odds ratios from the same predictor of different models cannot be compared directly. The y-standardization makes coefficients "comparable across models by dividing them with the estimated standard deviation of the latent variable for each model" (Mood 2010). Thus, whenever one has multiple logistic regression models that are fit to the same data and share certain predictors (e.g. nested models), it can be useful to use this standardization approach to make log-odds or odds ratios comparable.

Transformed Variables:

When the model's formula contains transformations (e.g. $y \sim exp(X)$) method = "refit" will give different results compared to method = "basic" ("posthoc" and "smart" do not support such transformations): While "refit" standardizes the data *prior* to the transformation (e.g. equivalent to exp(scale(X))), the "basic" method standardizes the transformed data (e.g. equivalent to scale(exp(X))).

See the *Transformed Variables* section in standardize.default() for more details on how different transformations are dealt with when method = "refit".

Confidence Intervals:

The returned confidence intervals are re-scaled versions of the unstandardized confidence intervals, and not "true" confidence intervals of the standardized coefficients (cf. Jones & Waller, 2015).

Generalized Linear Models:

Standardization for generalized linear models (GLM, GLMM, etc) is done only with respect to the predictors (while the outcome remains as-is, unstandardized) - maintaining the interpretability of the coefficients (e.g., in a binomial model: the exponent of the standardized parameter is the OR of a change of 1 SD in the predictor, etc.)

Dealing with Factors:

standardize(model) or standardize_parameters(model, method = "refit") do not standardize categorical predictors (i.e. factors) / their dummy-variables, which may be a different behaviour compared to other R packages (such as **lm.beta**) or other software packages (like SPSS). To mimic such behaviours, either use standardize_parameters(model, method = "basic") to obtain post-hoc standardized parameters, or standardize the data with datawizard::standardize(data, force = TRUE) before fitting the model.

Value

A data frame with the standardized parameters (Std_* , depending on the model type) and their CIs (CI_low and CI_high). Where applicable, standard errors (SEs) are returned as an attribute (attr(x, "standard_error")).

head(standardize_posteriors(model, method = "basic", verbose = FALSE))</pre>
```

standard_error Standard Errors

Description

standard_error() attempts to return standard errors of model parameters.

Usage

```
standard_error(model, ...)
## Default S3 method:
standard_error(
 model,
  component = "all",
 vcov = NULL,
 vcov_args = NULL,
 verbose = TRUE,
  . . .
)
## S3 method for class 'factor'
standard_error(model, force = FALSE, verbose = TRUE, ...)
## S3 method for class 'glmmTMB'
standard_error(
 model,
 effects = "fixed",
  component = "all",
 verbose = TRUE,
  • • •
)
## S3 method for class 'merMod'
standard_error(
 model,
 effects = "fixed",
 method = NULL,
 vcov = NULL,
 vcov_args = NULL,
  . . .
)
```

Arguments

model	A model.
	Arguments passed to or from other methods.
component	Model component for which standard errors should be shown. See the documen- tation for your object's class in model_parameters() or p_value() for further details.
νςον	Variance-covariance matrix used to compute uncertainty estimates (e.g., for ro- bust standard errors). This argument accepts a covariance matrix, a function which returns a covariance matrix, or a string which identifies the function to be used to compute the covariance matrix.

• A covariance matrix

	 A function which returns a covariance matrix (e.g., stats::vcov())
	• A string which indicates the kind of uncertainty estimates to return.
	 Heteroskedasticity-consistent: "vcovHC", "HC", "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". See ?sandwich::vcovHC.
	 Cluster-robust: "vcovCR", "CR0", "CR1", "CR1p", "CR1S", "CR2", "CR3". See ?clubSandwich::vcovCR.
	 Bootstrap: "vcovBS", "xy", "residual", "wild", "mammen", "webb". See ?sandwich::vcovBS.
	 Other sandwich package functions: "vcovHAC", "vcovPC", "vcovCL", "vcovPL".
vcov_args	List of arguments to be passed to the function identified by the vcov argument. This function is typically supplied by the sandwich or clubSandwich packages. Please refer to their documentation (e.g., ?sandwich::vcovHAC) to see the list of available arguments.
verbose	Toggle warnings and messages.
force	Logical, if TRUE, factors are converted to numerical values to calculate the stan- dard error, with the lowest level being the value 1 (unless the factor has numeric levels, which are converted to the corresponding numeric value). By default, NA is returned for factors or character vectors.
effects	Should standard errors for fixed effects ("fixed"), random effects ("random"), or both ("all") be returned? Only applies to mixed models. May be abbreviated. When standard errors for random effects are requested, for each grouping factor a list of standard errors (per group level) for random intercepts and slopes is returned.
method	Method for computing degrees of freedom for confidence intervals (CI) and the related p-values. Allowed are following options (which vary depending on the model class): "residual", "normal", "likelihood", "satterthwaite", "kenward", "wald", "profile", "boot", "uniroot", "ml1", "betwithin", "hdi", "quantile", "ci", "eti", "si", "bci", or "bcai". See section <i>Confi- dence intervals and approximation of degrees of freedom</i> in model_parameters() for further details.

Value

A data frame with at least two columns: the parameter names and the standard errors. Depending on the model, may also include columns for model components etc.

Note

For Bayesian models (from **rstanarm** or **brms**), the standard error is the SD of the posterior samples.

Examples

```
model <- lm(Petal.Length ~ Sepal.Length * Species, data = iris)
standard_error(model)</pre>
```

```
if (require("sandwich") && require("clubSandwich")) {
  standard_error(model, vcov = "HC3")
  standard_error(model,
    vcov = "vcovCL",
    vcov_args = list(cluster = iris$Species)
  )
}
```
