Description

This package contains functions used to perform fuzzy and hard clustering of vegetation data under different models.

Details

| Package: | vegclust |
| Type:    | Package |
| Version: | 1.6.3    |
| Date:    | 2013-07-01 |
| License: | GPL (>= 2) |
| LazyLoad:| yes |

This package is intended to be helpful for generating and maintaining classifications of vegetation. There are two main functions: (1) `vegclust` is used to create a fuzzy classification from an initial data set (a set of releves of community composition); (2) `vegclass` is used to classify new data (i.e. new releves) into previous classification structures.

Maintainer: Miquel De Cáceres <miquelcaceres@gmail.com>

References

Examples

```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1,
                           sqrt(rowSums(as.matrix(wetland)^2)), "/")

## Create noise clustering with 3 clusters. Perform 10 starts from random seeds
## and keep the best solution
wetland.nc = vegclust(wetland.chord, mobileCenters=3, m = 1.2, dnoise=0.75,
                        method="NC", nstart=10)
```

---

`as.memb`  
_Turns into membership matrix_

Description

Attempts to turn its cluster vector argument into a membership matrix

Usage

`as.memb(cluster)`

Arguments

- `cluster` A vector indicating the hard membership of each object in `x` to a set of groups. Can contain `NA` values.

Value

An matrix with as many rows as the length of `cluster` and as many columns as different cluster levels. `NA` values will have zero membership to all clusters
**Author(s)**
Miquel De Cáceres, Forest Science Center of Catalonia.

**See Also**
vegclust, vegclass

**Examples**
```
as.memb(factor(c(1,2,NA)))
```

---

**as.vegclust**

*Turns into vegclust objects*

**Description**
Attempts to turn its arguments into a vegclust object

**Usage**
```
as.vegclust(x, y, method="KM", m=1.0, dnoise=NULL, eta=NULL)
```

**Arguments**
- **x** A site-by-species data matrix (raw mode), or a site-by-site distance matrix (distance mode).
- **y** A vector indicating the cluster that each object in x belongs to. Alternatively, a fuzzy/hard site-by-group matrix of membership values.
- **method** A clustering model from which y was obtained (normally "KM"). Current accepted models are:
  - "KM": K-means or hard c-means (MacQueen 1967)
  - "KMdd": Hard c-medoids (Krishnapuram et al. 1999)
  - "FCM": Fuzzy c-means (Bezdek 1981)
  - "FCMdd": Fuzzy c-medoids (Krishnapuram et al. 1999)
  - "NC": Noise clustering (Dave and Krishnapuram 1997)
  - "NCdd": Noise clustering with medoids
  - "HNC": Hard noise clustering
  - "HNCdd": Hard noise clustering with medoids
  - "PCM": Possibilistic c-means (Krishnapuram and Keller 1993)
  - "PCMdd": Possibilistic c-medoids
- **m** The fuzziness exponent to be used, relevant for all fuzzy models (FCM, FCMdd, NC, NCdd, PCM and PCMdd)
- **dnoise** The distance to the noise cluster, relevant for noise clustering models (NC, HNC, NCdd and HNCdd).
- **eta** A vector of reference distances, relevant for possibilistic models (PCM and PCMdd).
Details
This function is used to generate `vegclust` objects which can then be used in `vegclass` to classify new data. If the input classification is hard (i.e. yes/no membership), cluster centers are calculated as multivariate means, and the method for assigning new data is assumed to be k-means ("KM"), i.e. plots will be assigned to the nearest cluster center. If community data is given as site-by-species data matrix the cluster centroids are added as `mobilecenters` in the `vegclust` object. Centroids will not be computed if community data is given as a site-by-site dissimilarity matrix. Moreover, current implementation does not allow y to be a membership matrix when x is a distance matrix.

Value
An object of class `vegclust`.

Author(s)
Miquel De Cáceres, Forest Science Center of Catalonia.

See Also
`vegclust`, `vegclass`

Examples
```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1,
  sqrt(rowSums(as.matrix(wetland)^2))), "/")

## Splits wetland data into two matrices of 30x27 and 11x22
wetland.30 = wetland.chord[1:30,]
wetland.30 = wetland.30[,colSums(wetland.30)>0]
dim(wetland.30)
wetland.11 = wetland.chord[31:41,]
wetland.11 = wetland.11[,colSums(wetland.11)>0]
dim(wetland.11)

## Performs a K-means clustering of the data set with 30 sites
wetland.km = kmeans(wetland.30, centers=3, nstart=10)

## Transforms the 'external' classification of 30 sites into a 'vegclust' object
wetland.30.vc = as.vegclust(wetland.30, wetland.km$cluster)

## Assigns the second set of sites according to the (k-means) membership rule
## That is, sites are assigned to the cluster whose cluster centroids is nearest.
wetland.11.km = vegclass(wetland.30.vc, wetland.11)

## A similar 'vegclust' object is obtained when using the distance mode...
wetland.d.vc = as.vegclust(dist(wetland.30), wetland.km$cluster)
```
CAP

_Cummulative abundance profile (CAP)_

### Description

Functions to calculate cumulative abundance profiles (CAPs), to build matrices from them, and to average profiles.

### Usage

`CAP(x, transform=NULL)`  
`CAP2matrix(CAP, type="profile", classWidths=NULL)`  
`CAPmeans(CAP, factor=NULL)`

### Arguments

- **x**: A stratified vegetation data set (see function `stratifyvegdata`).
- **transform**: A function or the name of a function to be applied to each cumulative abundance value.
- **CAP**: An object of class 'CAP'.
- **type**: The type of information that the resulting matrix should contain. Either "profile", "abundance" or "volume".
- **classWidths**: A numerical vector containing the width for size class (or vegetation stratum). If `NULL`, then all classes are assumed to have the same width.
- **factor**: A factor to calculate average profiles per each level.

### Details

Function `CAP` replaces the abundance value of a size class by the sum of abundances in this and larger size classes (strata). Thus, upper classes contain smaller abundance values than lower classes, creating a cumulative abundance profile. Function `CAP2matrix` takes an object of class 'CAP' and returns a data matrix, where values differ depending on parameter type: (1) type="profile" simply reshapes the 'CAP' object (a list) into a matrix with as many rows as plot records and where columns are organized in blocks (there are as many blocks as species and each block has as many columns as size classes); (2) type="abundance" returns a plot-by-species matrix where each value is the total abundance of the species in the plot (i.e. the CAP value at the ground level); (3) type="volume" returns a plot-by-species matrix where each value is the sum of CAP values across size classes (a measure of the "volume" occupied by the species in the plot). When provided, `classWidths` are used to weight size classes of the cumulative abundance profiles (for (1) and (3) only). Function `CAPmeans` calculates the average abundance profile for a set of plot records. If supplied, `factor` can be used to specify groups of samples for which average profiles are to be calculated.
Value

Function CAP returns an object of class 'CAP', similar to objects of class 'stratifiedvegdata' but where abundance values of upper size classes have been added to those of lower size classes. Function CAP2matrix returns a matrix with species as rows (columns depend on the value of type).

Examples

```r
## Load stratified data
data(medreg)

## Check that 'medreg' has correct class
class(medreg)

## Look at the data for the third plot
medreg[[3]]

## Create cumulative abundance profile (CAP) for each plot
medreg.CAP = CAP(medreg)

## Look at the profile of the third plot
medreg.CAP[[3]]

## Create matrix with species abundances
medreg.X = CAP2matrix(medreg.CAP, type="abundance")
head(medreg.X)

## Generate average profile
average.CAP = CAPmeans(medreg.CAP)

## Plot average profile
plot(average.CAP)
```
clustcentroid  Cluster centers of a classification

Description

Function clustcentroid calculates the centroid (multivariate average) coordinates of a classification. Function clustmedoid determines the medoid (object whose average dissimilarity to all the other objects is minimal) for each cluster in the classification.

Usage

clustcentroid(x, y, m = 1)
clustmedoid(x, y, m = 1)

Arguments

x  Community data, a site-by-species data frame. In function clustmedoid, x can alternatively be an object of class dist (otherwise, the dissimilarity measure is assumed to be the Euclidean distance).

y  It can be (a) A vector indicating the cluster that each object in x belongs to; (b) a fuzzy/hard site-by-group matrix of membership values; (c) an object of class vegclust or vegclass

m  Fuzziness exponent, only effective when y is a fuzzy membership matrix.

Value

Function clustcentroid returns a group-by-species matrix containing species average abundance values (i.e. the coordinates of each cluster centroid). Function clustmedoid returns a vector of indices (medoids).

Note

In order to assign new plot record data into a predefined set of classes, one should use functions as.vegclust and vegclass instead.

as.vegclust, vegclass, vegclust, kmeans
Examples

```r
## Loads stats
library(stats)

## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1,
    sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Performs a K-means clustering
wetland.km = kmeans(wetland.chord, centers=3, nstart=10)

## Gets the coordinates corresponding to the centroids of KM clusters
clustcentroid(wetland.chord, y=wetland.km$cluster)

## Gets the object indices corresponding to the medoids of KM clusters
clustmedoid(wetland.chord, y=wetland.km$cluster)
```

clustconst

**Constancy table of a classification**

Description

Allows studying the constancy table (i.e. the frequency of species in each class) of a classification represented in the form of a membership data matrix.

Usage

```r
clustconst(x, memb)
```

## S3 method for class 'clustconst'
summary(object, mode="all", name=NULL, sort=TRUE, minconst=0.5, digits=3, ...)

Arguments

- `x`: Community data, a site by species data frame.
- `memb`: An site-by-group matrix indicating the (hard or fuzzy) membership of each object in `x` to a set of groups.
- `object`: An object of class 'clustconst'.
- `mode`: Use mode="all" to print the constancy table, mode="cluster" to print constancy values for one cluster, and mode="species", to print constancy values for one species.
clustconst

- **name**: A string with the name of a cluster (in mode="cluster"), or the name of a species (in mode="species").
- **sort**: A flag to indicate whether constancy table should be sorted in descending order.
- **minconst**: A threshold used to limit the values shown.
- **digits**: The number of digits for rounding.
- **...**: Additional parameters for summary (actually not used).

**Details**

The constancy value of a species in a vegetation unit is the relative frequency of occurrence of the species in plot records that belong to the unit. In case of a fuzzy vegetation unit the constancy value is the sum of memberships of sites that contain the species divided by the sum of memberships of all sites. Use the 'summary' function to obtain information about: (1) which species are more frequent on a given vegetation unit; (2) which vegetation units have higher frequencies of a given target species. Additionally, the 'summary' function can sort a constancy table if mode="all" and sort=TRUE are indicated.

**Value**

Function clustconst returns an object of type 'clustconst', in fact a data frame with the constancy value of each species (rows) on each cluster (column).

**Author(s)**

Miquel De Cáceres, Forest Science Center of Catalonia

**See Also**

vegclust, kmeans

**Examples**

```r
## Loads stats
library(stats)

## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, sqrt(rowSums(as.matrix(wetland)^2))), ",/")

## Performs a K-means clustering
wetland.km = kmeans(wetland.chord, centers=3, nstart=10)

## Gets constancy table of KM (i.e. hard) clusters
c=clustconst(wetland.chord, memb=as.memb(wetland.km$cluster))

## Prints constancy values ordered and store the result in d
```
clustvar

```
d=summary(c, mode="all")

## Prints the most frequent species in the first cluster
summary(c, mode="cluster", name=names(c)[1])
```

clustvar

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computes the variation in community composition (i.e., beta diversity) found within the sites of a set of hard or fuzzy clusters.</td>
</tr>
</tbody>
</table>

Usage

```
clustvar(x, cluster = NULL, defuzzify=FALSE,...)
```

Arguments

- **x** Community data. Either a site-by-species matrix or a site-by-site matrix of compositional distances between sites (i.e., an object of class `dist`). Alternatively, this can be an object of class `vegclust` or `vegclass`, and in this case it is unnecessary to provide `cluster`.
- **cluster** A vector indicating the hard membership of each object in `x` to a set of groups.
- **defuzzify** A flag indicating whether fuzzy memberships should be defuzzified (see function `defuzzify`). Only applies to the case where an object of class `vegclust` or `vegclass` is supplied in `x`.
- **...** Additional parameters for function `defuzzify`.

Details

This function can be used in two ways:

- if `x` is a data matrix (site by species or distances among sites) and `cluster` is null, the function assumes a single cluster of all points in `x`. When `cluster` is provided, the function computes cluster variance for each (hard) group and this computation implies setting the centroid of the group. Cluster variance is defined as the average squared distance to the centroid.

- If `x` is an object of class `vegclust` or `vegclass`, the function uses the information contained there (distances to cluster centers, memberships and exponent of fuzziness) in order to compute cluster variances. Cluster centers do not need to be recomputed, and the distances to cluster centers are used directly. For centroid-based cluster models (KM, FCM, NC, HNC and PCM) the variance is defined as the average squared distance to the centroid. For medoid-based cluster models (KMdd, FCMdd, NCdd, HNCdd and PCMdd) the variance is defined as average distance to the medoid. The variance for both mobile and fixed clusters is returned. Additionally, membership matrices may be defuzzified if `defuzzify=TRUE`. 
Value
A double value (for one cluster) or a vector of values, one per each cluster.

Author(s)
Miquel De Cáceres, Forest Science Center of Catalonia

See Also
vegclust, kmeans, defuzzify

Examples

```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1,
sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Create noise clustering with 3 clusters. Perform 10 starts from random seeds
## and keep the best solution
wetland.nc = vegclust(wetland.chord, mobileCenters=3, m = 1.2, dnoise=0.75,
method="NC", nstart=10)

## Gets cluster variance of fuzzy clusters
clustvar(wetland.nc)

## Gets cluster variance of fuzzy clusters after defuzzification
clustvar(wetland.nc, defuzzify=TRUE)

## Similar to the previous, this gets cluster variance of defuzzified (i.e. hard) clusters
clustvar(wetland.chord, cluster=defuzzify(wetland.nc)$cluster)

## Gets cluster variance of K-means (i.e. hard) clusters
clustvar(wetland.chord, cluster=kmeans(wetland.chord, centers=3, nstart=10)$cluster)
```

conformveg  Conform two community data tables

Description
Conforms two community data tables to have the same set of columns (species)

Usage
conformveg(x, y, fillvalue = 0, verbose=FALSE)
**Arguments**

- **x**  
  Community data, a site-by-species matrix.

- **y**  
  Community data, a site-by-species matrix.

- **fillvalue**  
  The value to be used to fill new entries in inflated matrices.

- **verbose**  
  Displays information about the number of species shared between x and y, as well as the number of species that are in one of the data tables but not in the other.

**Details**

This function adds to x as many new columns as columns of y that are not in x. The same is done for y, so the two tables have the same set of columns when they are returned.

**Value**

A list with the two inflated matrices x and y.

**Author(s)**

Miquel De Cáceres, Centre Tecnologic Forestal de Catalunya.

**See Also**

- vegclust, vegclass

**Examples**

```r
## Loads data (38 columns and 33 species)
data(wetland)
dim(wetland)

## Splits wetland data into two matrices of 30x27 and 11x22
wetland.30 = wetland[1:30,]
wetland.30 = wetland.30[,colSums(wetland.30)>0]
dim(wetland.30)
wetland.11 = wetland[31:41,]
wetland.11 = wetland.11[,colSums(wetland.11)>0]
dim(wetland.11)

## Conforms the two matrices so they can eventually be merged
wetland.cf = conformveg(wetland.30, wetland.11)
dim(wetland.cf$x)
dim(wetland.cf$y)
names(wetland.cf$x)==names(wetland.cf$y)
```
Cross-table of two fuzzy classifications

Description

Calculates a cross-tabulated matrix relating two fuzzy membership matrices.

Usage

crossmemb(x, y, relativize = TRUE)

Arguments

x

A site-by-group fuzzy membership matrix. Alternatively, an object of class 'vegclust' or 'vegclass'.

y

A site-by-group fuzzy membership matrix. Alternatively, an object of class 'vegclust' or 'vegclass'.

relativize

If TRUE expresses the cross-tabulated values as proportions of cluster size in x.

Value

A cross-tabulated matrix comparing the two classifications. In general, each cell's value is the (fuzzy) number of objects that in x are assigned to the cluster corresponding to the row and in y are assigned to the cluster corresponding to the column. If relativize=TRUE then the values of each row are divided by the (fuzzy) size of the corresponding cluster in x.

Author(s)

Miquel De Cáceres, Forest Science Center of Catalonia.

See Also

defuzzify, vegclust

Examples

```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1,
                              sqrt(rowSums(as.matrix(wetland)^2)), "/")

## Create clustering with 3 clusters. Perform 10 starts from random seeds
## and keep the best solution. Try both FCM and NC methods:
wetland.fcm = vegclust(wetland.chord, mobileCenters=3, m = 1.2, method="FCM", nstart=10)
```
defuzzify

wetland.nc = vegclust(wetland.chord, mobileCenters=3, m = 1.2, dnoise=0.75, method="NC", nstart=10)

## Compare the results
crossmemb(wetland.fcm, wetland.nc, relativize=FALSE)

defuzzify  Defuzzifies a fuzzy partition

Description
Transforms a fuzzy classification into a crisp (hard) classification.

Usage
defuzzify(object, method = "max", alpha = 0.5, na.rm = FALSE)

Arguments
object  A site-by-group fuzzy membership matrix. Alternatively, an object of class ‘vegclust’ or ‘vegclass’.
method  Either "max" to choose for the maximum membership value across clusters, or "cut" for an alpha-cut.
alpha  Threshold for the alpha-cut, bounded between 0 and 1.
na.rm  If TRUE removes the objects that do not belong to any cluster when using method="cut".

Details
Alpha-cut means that memberships lower than alpha are transformed into 0 while memberships higher than alpha are transformed into 1. This means that if alpha values are low (i.e. close to 0), an object may belong to more than one group after defuzzification. These will generate a concatenation of cluster names in the output cluster vector and a row with sum more than one in the memb matrix). Similarly, if alpha is high (i.e. close to 1) there are objects that may be left unclassified. These will get NA in the cluster vector and zero row in the memb matrix.

Value
A list with the following items:

memb  A data frame with the hard membership partition.
cluster  A vector (factor) with the name of the cluster for each object.

Author(s)
Miquel De Cáceres, Forest Science Center of Catalonia.

  method="NC", nstart=10)

## Defuzzification using an alpha-cut (alpha=0.5)
wetland.nc.df = defuzzify(wetland.nc$memb, method="cut")

## Cluster vector, with 'N' for objects that are unclassified,
## and 'NA' for objects that are intermediate
print(wetland.nc.df$cluster)

## Hard membership matrix (site 22 does not get any cluster assigned)
print(wetland.nc.df$memb)
```

---

### hcr

#### Heterogeneity-constrained random resampling (HCR)

**Description**

Returns a set of indices of the original data set that maximizes the mean and minimizes the variance of the distances between pairs of plot records.

**Usage**

```r
hcr(d, nout, nsampl=1000)
```
Arguments
  d  An object of class dist containing the distance values between pairs of sites (plot records).
  nout The number of sites (plot records) to be chosen among those available in d.
  nsampl The number of resampling trials to be compared.

Details
Many subsets of the input data are selected randomly. These subsets are sorted by decreasing mean
dissimilarity between pairs of plot records, and then sorted again by increasing variance of these
dissimilarities. Ranks from both sortings are summed for each subset, and the subset with the lowest
summed rank is considered as the most representative.

Value
Returns a vector containing the indices of the selected sites (plot records) to be used for sub-setting
the original table.

Author(s)
Miquel De Cáceres, Forest Science Center of Catalonia

References
Lengyel, A., Chytry, M., Tichy, L. (2011) Heterogeneity-constrained random resampling of phy-

Examples
## Loads data (38 columns and 33 species)
data(wetland)
dim(wetland)

## Constructs the chord distance matrix
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = dist(as.data.frame(sweep(as.matrix(wetland), 1,
  sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Performs HCR resampling. Returns indices of objects
sel = hcr(wetland.chord, nout=20, nsampl=1000)

## Prints the names of the plot records
print(row.names(wetland)[sel])

## Subset the original distance matrix
sel.chord = as.dist(as.matrix(wetland.chord)[sel, sel])
hier.vegclust  Clustering with several number of clusters

Description

Performs several runs of function `vegclust` on a community data matrix using different number of clusters.

Usage

hier.vegclust(x, hclust, cmin=2, cmax=20, verbose=TRUE, ...)
random.vegclust(x, cmin=2, cmax=20, nstart=10, verbose=TRUE, ...)

Arguments

- x: Community data table. A site (rows) by species (columns) matrix or data frame.
- hclust: A hierarchical clustering represented in an object of type `hclust`.
- cmin: Number of minimum mobile clusters.
- cmax: Number of maximum mobile clusters.
- nstart: A number indicating how many random trials should be performed for each number of groups.
- verbose: Flag used to print which number of clusters is currently running.
- ...: Additional parameters for function `vegclust`.

Details

Function `hier.vegclust` takes starting cluster configurations from cuts of a dendrogram given by object `hclust`. Function `random.vegclust` chooses random objects as cluster centroids and for each number of clusters performs `nstart` trials.

Value

Returns an object of type `'mvegclust'` (multiple vegclust), which contains a list vector with objects of type `vegclust`.

Author(s)

Miquel De Cáceres, Forest Science Center of Catalonia

See Also

`vegclust, vegclass, defuzzify, hclust`
Examples

```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Create noise clustering from hierarchical clustering at different number of clusters
wetland hc = hclust(dist(wetland.chord), method="ward")
wetland.nc1 = hier.vegclust(wetland.chord, wetland hc, cmin=2, cmax=5, m=1.2, dnoise=0.75, method="NC")

## Create noise clustering from random seeds at different levels
wetland.nc2 = random.vegclust(wetland.chord, cmin=2, cmax=5, nstart=10, m=1.2, dnoise=0.75, method="NC")
```

---

**incr.vegclust**

*Noise clustering with increasing number of clusters*

Description

Performs several runs of function `vegclust’ on a community data matrix using an increasing number of clusters until some conditions are met.

Usage

```r
incr.vegclust(x, method="NC", ini.fixed.centers = NULL, min.size = 10, alpha = 0.5, nstart=100, fix.previous = TRUE, ...)
```

Arguments

- **x**
  Community data table. A site (rows) by species (columns) matrix or data frame.
- **method**
  A clustering model. Current accepted models are of the noise clustering family:
  - "NC": Noise clustering (Dave and Krishnapuram 1997)
  - "NCdd": Noise clustering with medoids
  - "HNC": Hard noise clustering
  - "HNcd": Hard noise clustering with medoids
- **ini.fixed.centers**
  The coordinates of initial fixed cluster centers. These will be used as fixedCenters in all calls to `vegclust`.
- **min.size**
  The minimum size (cardinality) of clusters. If any of the current k clusters does not have enough members the algorithm will stop and return the solution with k-1 clusters.
alpha  Criterion to choose cluster seeds from the noise class. Specifically, an object is considered as cluster seed if the membership to the noise class is larger than alpha.

nstart  A number indicating how many random trials should be performed for number of groups. Each random trial uses the k-1 cluster centers plus the coordinates of the current cluster seed as initial solution for vegclust. Thus, if there are less cluster seed candidates than nstart, then not all runs are conducted.

fix.previous  Flag used to indicate that the cluster centers found when determining k-1 clusters are fixed when determining k clusters.

...  Additional parameters for function vegclust (normally dnoise and m).

Details
Function hier.vegclust takes starting cluster configurations from cuts of a dendrogram given by object hclust. Function random.vegclust chooses random objects as cluster centroids and for each number of clusters performs nstart trials.

Value
Returns an object of class vegclust; or NULL if the initial cluster does not contain enough members.

Examples
```r
## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Call incremental noise clustering
wetland.nc = incr.vegclust(wetland.chord, method="NC", m = 1.2, dnoise=0.75, min.size=5)

## Inspect cluster sizes
print(wetland.nc$size)
```
interclustdist  

Calculates the distance between pairs of cluster centroids

Description

Calculates the distance between pairs of cluster centroids, given a distance matrix and a cluster vector.

Usage

interclustdist(x, cluster)

Arguments

x  
A site-by-site data matrix or an object of class dist containing the distance values between pairs of sites (plot records).

cluster  
A vector indicating the hard membership of each object in x to a set of groups. Can contain NA values.

Value

An object of class dist containing the distances between cluster centers.

Author(s)

Miquel De Cáceres, Forest Science Center of Catalonia

Examples

##TO BE DONE##

medreg  

Regeneration of Mediterranean vegetation data set

Description

A stratified vegetation data set containing with several plot records laid to assess vegetation recovery three years after a wildfire. Collected in 2012 by Miquel De Caceres and Albert Petit in Horta de Sant Joan (Catalonia, Spain).

Usage

data(medreg)
Format

An object of class 'stratifiedvegdata' with 96 elements (plots), each of them consisting of a data.frame where rows correspond to species groups and columns correspond to vegetation strata. Abundance values are percentage cover.

See Also

stratifyvegdata

Examples

data(medreg)

plot.CAP  

| plot.CAP | Plots cumulative abundance profiles |

Description

Create plots used to inspect one or more cumulative abundance profiles.

Usage

```r
## S3 method for class 'CAP'
plot(x, sizes=NULL, species=NULL, plots=NULL, switchAxes=FALSE, add=FALSE,
     xlab="", ylab="", ...)```

Arguments

- `x` An object returned from function `CAP`.
- `sizes` A vector containing the (maximum) size values associated to each size class. If NULL the y-axis will be defined using the size class order in x.
- `species` A vector of strings indicating the species whose profile is to be drawn. If NULL all species are plotted.
- `plots` A vector of strings indicating the plot records whose profile is to be drawn. If NULL all plot records are plotted.
- `switchAxes` A flag indicating whether ordinate and abscissa axes should be interchanged.
- `add` A flag indicating whether profiles should be drawn on top of current drawing area. If add=FALSE a new plot is created.
- `xlab` String label for the x axis.
- `ylab` String label for the y axis.
- `...` Additional plotting parameters.

## Check that 'medreg' has correct class
class(medreg)

## Create cumulative abundance profile (CAP) for each plot
medreg.CAP = CAP(medreg)

## Draw the profile corresponding to the third plot
plot(medreg.CAP, plots="3")

## Look at the profile itself
medreg.CAP[[3]]

plot.mvegclust  Plots clustering results

Description
Create plots used to study vegclust clustering results for an increasing number of clusters

Usage
## S3 method for class 'mvegclust'
plot(x, type="hnc", excludeFixed=TRUE, verbose=FALSE, ylim=NULL,
    xlab=NULL, ylab=NULL, maxvar=0.6, minsize=20,...)

Arguments
x                   An object returned from functions hier.vegclust or random.vegclust.
type                A string indicating the type of plot desired. Current accepted values are "hnc","hmemb","var","hcs" and "valid".
excludeFixed        A flag to indicate whether clusters with fixed centroids should be excluded from plots.
verbose             A flag to print extra information.
ylim                A vector with the limits for the y axis.
plot.mvegclust

   xlab        String label for the x axis.
   ylab        String label for the y axis.
   maxvar      Maximum cluster variance allowed for the type="valid" plot.
   minsize     Minimum cluster size allowed for the type="valid" plot.
   ...         Additional plotting parameters.

Value

Different information is returned depending on the type of plot chosen.

Author(s)

Miquel De Cáceres, Forest Science Center of Catalonia

Examples

## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package 'vegan')
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, 
   sqrt(rowSums(as.matrix(wetland)^2)), ")/"))

## Create noise clustering from hierarchical clustering at different number of clusters
wetland hc = hclust(dist(wetland.chord), method="ward")
wetland nc = hier.vegclust(wetland.chord, wetland.hc, cmin=2, cmax=5, m = 1.2, 
dnoise=0.75, method="NC")

## Plot changes in the number of objects falling into the noise cluster
plot(wetland.nc, type="hnc")

## Plots the number of objects falling into "true" clusters,
## the number of objects considered intermediate,
## and the number of objects falling into the noise
plot(wetland.nc, type="hmemb")

## Plot minimum, maximum and average cluster size
plot(wetland.nc, type="hcs")

## Plot minimum, maximum and average cluster variance
plot(wetland.nc, type="var")

## Plot number of groups with high variance, low membership or both
plot(wetland.nc, type="valid")
relate.levels  

Relates two clustering level results.

Description

Analyzes how lower level clusters are assigned into upper level ones. The analysis is made for several number of clusters.

Usage

relate.levels(lower, upper, defuzzify = FALSE, excludeFixed = FALSE, verbose=FALSE, ...)

Arguments

lower  A list of objects of type vegclust or vegclass that represent classifications at a finer level of resolution.
upper  A list of objects of type vegclust or vegclass that represent classifications at a broader level of resolution.
defuzzify A logical flag used to indicate whether the result of calling crossmemb should be defuzzified.
excludeFixed A logical used to indicate whether fixed clusters should be excluded from the comparison of levels.
verbose A flag used to ask for extra screen output.
... Additional parameters for function defuzzify.

Details

For each pair of vegclust (or vegclass) objects in upper and lower, the function calls function crossmemb and then, if asked, deffuzzifies the resulting memberships (by calling function defuzzify) and several quantities are calculated (see ‘value’ section).

Value

A list with several data frames (see below). In each of them, the rows are items of upper and columns are items of lower. The names of rows and columns are the number of clusters of each vegclust (or vegclass) object.

- nnoise  The number of low level clusters that are assigned to the Noise class (for upper objects using Noise clustering).
- maxnoise  The maximum membership value of low level clusters to the Noise class (for upper objects using Noise clustering).
- minmaxall  The minimum value (across upper level clusters) of the maximum membership value observed among the lower level clusters.
- minallsize  The minimum value (across upper level clusters) of the sum of membership values across lower level clusters.
- empty  The number of upper level clusters (mobile or fixed) that do not have any member among the lower level clusters.
stratifyvegdata

Reshapes community data from individual into stratified form

Description

Function stratifyvegdata reshapes individual abundance values into species abundance values per size class (stratum). Function as.stratifiedvegdata checks if the input list has appropriate properties and turns it into an object of class 'stratifiedvegdata'.

Usage

stratifyvegdata(x, sizes, plotColumn="plot", speciesColumn = "species", 
abundanceColumn="abundance", sizeColumn = "size", counts=FALSE, 
mergeSpecies=FALSE)

as.stratifiedvegdata(X)

Arguments

x
A data frame containing individual plant data. Individuals are in rows, while measurements are in columns.
stratifyvegdata

- **sizes**: A numerical vector containing the minimum size for each size class (stratum) in ascending order.
- **plotColumn**: The name of the column in x that contains plot identifiers.
- **speciesColumn**: The name of the column in x that contains species names.
- **abundanceColumn**: The name of the column in x that contains abundance values.
- **sizeColumn**: The name of the column in x that contains size values.
- **counts**: A flag to indicate that the output should be individual counts instead of added abundance values.
- **mergeSpecies**: A flag to indicate that species identity should be ignored. This leads to analyzing the structure of biomass disregarding species identity.
- **x**: A list with as many elements as plot records. Each element should be of class 'matrix' or 'data.frame' with species in rows and strata in columns. Furthermore, the number of rows (species) and columns (strata) should be the same for all elements.

**Details**

For each individual (row) in x, stratifyvegdata assigns it to the size class (stratum) containing its size. The corresponding abundance value (e.g. crown cover) of the individual is added to the abundance of the corresponding species at the size class (stratum).

**Value**

Both functions return an object of class 'stratifiedvegdata', which is a list of data frames, one for each plot record. Each element (data frame) has as many rows as species and as many columns as size classes (i.e., as many as elements in vector sizes). Columns are named starting with 'S' and continuing with the size class (stratum) number. If mergeSpecies=TRUE then all data frames have a single row (whose name is "all").

**Author(s)**

Miquel De Cáceres, Forest Science Center of Catalonia.

reshape, CAP
Examples

```r
## Load tree data
data(treedata)

## Inspect tree data
head(treedata)

## Define stratum thresholds (4 strata)
heights = 0.5+(0:3)

## Stratify tree data
X = stratifyvegdata(treedata, sizes=heights, plotColumn="plotID",
speciesColumn="species", sizeColumn="height", counts=TRUE)

## Inspect the first plot record
X[[1]]
```

---

**treedata**

*Synthetic vegetation data set with tree data*

**Description**

A synthetic data set used to illustrate the stratification of data originally collected on an individual basis.

**Usage**

data(treedata)

**Format**

A data frame where each row corresponds to a different tree. Columns are plot code, species identity, tree height and cover value.

**See Also**

*stratifyvegdata*

**Examples**

```r
## Load tree data
data(treedata)

## Inspect tree data
head(treedata)

## Define stratum thresholds (4 strata)
heights = 0.5+(0:3)
```
## vegclass

**Classifies vegetation communities**

### Description

Classifies vegetation communities into a previous fuzzy or hard classification.

### Usage

```r
vegclass(y, x)
```

### Arguments

- `y`: An object of class `vegclust` that represents a previous knowledge.
- `x`: Community data to be classified, in form of a site by species matrix (if the `vegclust` object is in `raw` mode) or a data frame containing the distances between the new sites in rows and the old sites in columns (if the `vegclust` object is in `distance` mode).

### Details

This function uses the classification model specified in `y` to classify the communities (rows) in `x`. When `vegclust` is in `raw` mode, the function calls first to `conformveg` in order to cope with different sets of species. See the help of `as.vegclust` to see an example of `vegclass` with distance matrices.

### Value

Returns an object of type `vegclass` with the following items:

- `method`: The clustering model used in `y`
- `m`: The fuzziness exponent in `y`
- `dnoise`: The distance to the noise cluster used for noise clustering (models NC, NCdd, HNC, HNCdd). This is set to NULL for other models.
- `eta`: The reference distance vector used for possibilistic clustering (models PCM and PCMdd). This is set to NULL for other models.
- `memb`: The fuzzy membership matrix.
- `dist2clusters`: The matrix of object distances to cluster centers.

## Loads data (38 columns and 33 species)
data(wetland)
dim(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, 
    sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Splits wetland data into two matrices of 30x27 and 11x22
wetland.30 = wetland.chord[1:30,]
wetland.30 = wetland.30[,colSums(wetland.30)>0]
dim(wetland.30)
wetland.11 = wetland.chord[31:41,]
wetland.11 = wetland.11[,colSums(wetland.11)>0]
dim(wetland.11)

## Create noise clustering with 3 clusters from the data set with 30 sites.
wetland.30.nc = vegclust(wetland.30, mobileCenters=3, m = 1.2, dnoise=0.75, 
    method="NC", nstart=10)

## Cardinality of fuzzy clusters (i.e., the number of objects belonging to)
wetland.30.nc$size

## Classifies the second set of sites according to the clustering of the first set
wetland.11.nc = vegclass(wetland.30.nc, wetland.11)

## Fuzzy membership matrix
wetland.11.nc$mem

## Obtains hard membership vector, with 'N' for objects that are unclassified
```
Vegclust

Description
Performs hard or fuzzy clustering of vegetation data.

Usage
vegclust(x, mobilecentersL fixedcenters, mobilemembersL fixedmembers, method="NC", m=2, dnoise=NULL, eta=NULL, alpha=0.001, iter.max=100, nstart=1, maxminJ=10, seeds=NULL, verbose=FALSE)

Arguments
x Community data. A site-by-species matrix or data frame (for vegclust) or a site-by-site dissimilarity matrix or dist object (for vegclustdist).
mobilecenters A number, a vector of seeds, or coordinates for mobile clusters.
fixedcenters A matrix or data frame with coordinates for fixed (non-mobile) clusters.
mobilemembers A number, a vector of seeds, or starting memberships for mobile clusters.
fixedmembers A matrix or data frame with starting memberships for fixed (non-mobile) clusters.
method A clustering model. Current accepted models are:
• "KM": K-means or hard c-means (MacQueen 1967)
• "KMdd": Hard c-medoids (Krishnapuram et al. 1999)
• "FCM": Fuzzy c-means (Bezdek 1981)
• "FCMdd": Fuzzy c-medoids (Krishnapuram et al. 1999)
• "NC": Noise clustering (Dave and Krishnapuram 1997)
• "NCdd": Noise clustering with medoids
• "HNC": Hard noise clustering
• "HNCdd": Hard noise clustering with medoids
• "PCM": Possibilistic c-means (Krishnapuram and Keller 1993)
• "PCMdd": Possibilistic c-medoids
m The fuzziness exponent to be used (this is relevant for all models except for kmeans).
dnoise The distance to the noise cluster, relevant for noise clustering (NC).
eta A vector of reference distances, relevant for possibilistic C-means (PCM).
alpha

Threshold used to stop iterations. The maximum difference in the membership matrix of the current vs. the previous iteration will be compared to this value.

iter.max

The maximum number of iterations allowed.

nstart

If mobileCenters or mobileMemb is a number, how many random sets should be chosen?

maxminJ

When random starts are used, these will stop if at least maxminJ runs ended up in the same functional value.

seeds

If mobileCenters or mobileMemb is a number, a vector indicating which objects are potential initial centers. If NULL all objects are valid seeds.

verbose

Flag to print extra output.

Details

Functions vegclust and vegclustdist try to generalize the kmeans function in stats in three ways.

Firstly, they allows different clustering models. Clustering models can be divided in (a) fuzzy or hard; (b) centroid-based or medoid-based; (c) Partitioning (KM and FCM family), noise clustering (NC family), and possibilistic clustering (PCM and PCMdd). The reader should refer to the original publications to better understand the differences between models.

Secondly, users can specify fixed clusters (that is, centroids that do not change their positions during iterations). Fixed clusters are intended to be used when some clusters were previously defined and new data has been collected. One may allow some of these new data points to form new clusters, while some other points will be assigned to the original clusters. In the case of models with cluster repulsion (such as KM, FCM or NC) the new (mobile) clusters are not allowed to ‘push’ the fixed ones. As a result, mobile clusters will occupy new regions of the reference space.

Thirdly, vegclustdist implements the distance-based equivalent of vegclust. The results of vegclust and vegclustdist will be the same (if seeds are equal) if the distance matrix is calculated using the Euclidean distance (see function dist). Otherwise, the equivalence holds by resorting on principal coordinates analysis.

Note that all data frames or matrices used as input of vegclust should be defined on the same space of species (see conformveg). Unlike kmeans, which allows different specific algorithms, here updates of prototypes (centroids or medoids) are done after all objects have been reassigned (Forgy 1965). In order to obtain hard cluster definitions, users can apply the function defuzzify to the vegclust object.

Value

Returns an object of type vegclust with the following items:

mode

raw for function vegclust and dist for function vegclustdist.

method

The clustering model used

m

The fuzziness exponent used (m=1 in case of kmeans)

dnoise

The distance to the noise cluster used for noise clustering (NC, HNC, NCdd or HNCdd). This is set to NULL for other models.

eta

The reference distance vector used for possibilistic clustering (PCM or PCMdd). This is set to NULL for other models.
The fuzzy membership matrix. Columns starting with "M" indicate mobile clusters, whereas columns starting with "F" indicate fixed clusters.

If `vegclust` is used, this contains a data frame with the coordinates of the mobile centers (centroids or medoids). If `vegclustdist` is used, it will contain the indices of mobile medoids for models KMdd, FCMdd, HNCdd, NCdd and PCMdd; or NULL otherwise.

If `vegclust` is used, this contains a data frame with the coordinates of the fixed centers (centroids or medoids). If `vegclustdist` is used, it will contain the indices of fixed medoids for models KMdd, FCMdd, HNCdd, NCdd and PCMdd; or NULL otherwise.

The matrix of object distances to cluster centers. Columns starting with "M" indicate mobile clusters, whereas columns starting with "F" indicate fixed clusters.

In the case of methods KM, FCM, NC, PCM and HNC it contains the within-cluster sum of squares for each cluster (squared distances to cluster center weighted by membership). In the case of methods KMdd, FCMdd, NCdd, HNCdd and PCMdd it contains the sum of distances to each cluster (weighted by membership).

The number of objects belonging to each cluster. In case of fuzzy clusters the sum of memberships is given.

The objective function value (the minimum value attained after all iterations).

Examples

## Loads data
data(wetland)

## This equals the chord transformation
## (see also \code{\link{decostand}} in package vegan)
wetland.chord = as.data.frame(sweep(as.matrix(wetland), 1, sqrt(rowSums(as.matrix(wetland)^2)), "/"))

## Create noise clustering with 3 clusters. Perform 10 starts from random seeds
## and keep the best solution
wetland.nc = vegclust(wetland.chord, mobileCenters=3, m = 1.2, dnoise=0.75, method="NC", nstart=10)

## Fuzzy membership matrix
wetland.nc$memb

## Cardinality of fuzzy clusters (i.e., the number of objects belonging to each cluster)
wetland.nc=size

## Obtains hard membership vector, with 'N' for objects that are unclassified
defuzzify(wetland.nc$memb)$cluster

## The same result is obtained with a matrix of chord distances
wetland.d = dist(wetland.chord)
wetland.d.nc = vegclustdist(wetland.d, mobileMemb=3, m = 1.2, dnoise=0.75, method="NC", nstart=10)

vegclustIndex

## Compute fuzzy evaluation statistics

Description

Computes several evaluation statistics on the fuzzy clustering results on objects of class vegclust.

Usage

vegclustIndex(y)

Arguments

y An object of class vegclust or a membership matrix.
These statistics were conceived to be computed on fuzzy partitions, such as the ones coming from Fuzzy C-means (Bezdek 1981). Maximum values of PCN or minimum values of PEN can be used as criteria to choose the number of clusters.

Value

Returns a vector of four values: partition coefficient (PC), normalized partition coefficient (PCN), partition entropy (PE) and normalized partition entropy (PEN).

## Compute statistics. Both PCN and PEN indicate that three groups are more advisable
## than 2 or 4.
print(vegclustIndex(wetland.fcm2))
print(vegclustIndex(wetland.fcm3))
print(vegclustIndex(wetland.fcm4))
```
Description

Function to calculate the dissimilarity between plant communities taking into account both their composition and the size of organisms.

Usage

vegdiststruct(x, type=\"profile\", method=\"bray\", transform=NULL, classWidths=NULL)

Arguments

x A stratified vegetation data set (see function stratifyvegdata), or a set of cumulative abundance profiles (see function CAP).
type Whether dissimilarities between pairs of sites should be calculated from differences in cumulative abundance profiles (\"profile\"), in total species abundance (\"abundance\") or in volumes of cumulative abundance profiles (\"volume\")..
method The dissimilarity coefficient to calculate (see details).
transform A function or the name of a function to be applied to each cumulative abundance value.
classWidths A numerical vector containing the width for each size class (or stratum). If NULL, then the function assumes classes of equal width.

Details

The six different coefficients available are described in De Caceres et al. (in prep.): (1) method=\"bray\" for percentage difference (alias Bray-Curtis dissimilarity); (2) method=\"ruzicka\" for Ruzicka index (a generalization of Jaccard); (3) method=\"kulczynski\" for the Kulczynski dissimilarity index; (4) method=\"ochiai\" for the complement of a quantitative generalization of Ochiai index of similarity; (5) method=\"canberra\" for the Canberra index (Adkins form); (6) method=\"elman\" for the relativized Manhattan coefficient (Whittaker’s index of association).

Value

Returns an object of class \"dist\".

wetland  
Wetland vegetation data set

Description

Vegetation of the Adelaide river alluvial plain (Australia). This data set was published by Bowman & Wilson (1987) and used in Dale (1988) to compare fuzzy classification approaches.

Usage

data(wetland)

Format

A data frame with 41 sites (rows) and 33 species (columns). Abundance values are represented in abundance classes.

Source
